## Acknowledgements

This is an independent report commissioned and funded by the Policy Research Programme in the Department of Health. The views expressed are not necessarily those of the Department.

The team wishes to thank the many scientists in the alcohol policy field who generously shared knowledge and evidence, especially the three peer reviewers who despite very short timescales provided very valuable feedback.

## The team

This project team combined the strengths of The University of Sheffield's School of Health and Related Research (SchHARR), Department of Economics, and School of Management; and the University of Victoria's Centre for Addictions Research of British Columbia (CARBC), Canada.

**Petra Meier** works as Senior Lecturer in Public Health in SchHARR. Her research expertise is in the drugs and alcohol field. She has a special interest in the application of modelling in the medical and social sciences, having recently led a multi-disciplinary project on modelling policy interventions for gun crime. As principal investigator, she co-ordinated the team's efforts and advised the reviewers and modellers on issues to do with alcohol consumption and resulting harm. **Andrew Booth** is the Director of the SchHARR Section of Information Resources, which has been at the forefront of research on systematic review methodology for many years. With twenty five years' experience as a health information professional, he has published numerous systematic reviews of evidence across a range of health areas including for the NHS Health Technology Assessment Programme. His team (**Anthea Sutton**, **Anna Wilkinson** and **Ruth Wong**) completed the literature searches, reference management, document acquisition and production of evidence tables carried out the work for Phase 1, the systematic reviewing component of the study. **Tim Stockwell** (University of Victoria, British Columbia, Canada) is a leading expert in the field of alcohol policy and has carried out similar studies in Canada and elsewhere. He is currently director of the Centre for Addictions Research BC, a multi-site and multi-campus enterprise dedicated to research and communication evidence-based approaches to reducing alcohol and other drug related harm. **Alan Brennan** (Director of the Health Economics and Decision Sciences Section, SchHARR) is a senior modeller who has been developing models in support of healthcare decision-making nationally and internationally across a large range of diseases, interventions and policy issues. His responsibility is to oversee Phase 2 of the project, the modelling of the effects of policy interventions. **Daragh O'Reilly** (Marketing Research Group, School of Management) researches the link between marketing, branding and consumption. He is the past chair of the Academy of Marketing's Group on Social Marketing. He contributed valuable expertise in the current thinking around promotional practices. **Robin Purshouse** (Health Economics and Decision Sciences, SchHARR) has developed models to support government decision makers in a variety of policy and implementation areas. **Karl Taylor** (School of Economics) is a senior economist specialising in applied microeconometrics and led the work on economic parameters. He leads on the estimation of price and promotion elasticities.

## Structure of the report

The report commences with an overview of the aims and objectives of the research, followed by a brief outline of key trends in alcohol consumption, alcohol related harm and the alcohol market. Next, there is a short section detailing our understanding of current alcohol advertising and promotion strategies as relevant to the UK market and the regulatory framework guiding UK alcohol marketing activities. We end with the three review reports. This report is accompanied by the report *Modelling the Potential Impact Of Pricing And Promotion Policies For Alcohol In England: Results From The Sheffield Alcohol Policy Model*.

## Overview

This report presents the results of the first phase of an investigation into the effects of pricing and promotion on alcohol consumption and related harm in the UK, commissioned through the Policy Research Programme, National Institute for Health Research, Department of Health.

Recent research on alcohol policies has made it possible to rank policies and interventions according to their effectiveness in controlling excessive alcohol use and alcohol-related harm. The evidence suggests that there are a large range of effective strategies from which policy decision-makers can choose (Jahiel & Babor 2007, Stockwell et al 2006). However, it appears that some ineffective strategies tend to be particularly fashionable whereas strategies that are more effective can be unpopular (Brand et al, 2007). The English Government recently published the updated National Alcohol Strategy (Department of Health, 2007), which, among other things, proposes to tackle those pricing, marketing and promotional practices which may harm alcohol consumers, especially those most vulnerable to the negative effects of alcohol. A policy that leads to price increases of alcoholic beverages is likely to be one of the less popular policy choices, with both consumers and industry, and policies restricting promotional activity could potentially have significant detrimental influences on the alcohol industry. Therefore, it is imperative that such policy decisions are based on a sound evaluation of existing evidence (Phase 1 of our work) and pre-testing of the likely impacts of policy changes (Phase 2).

## Aims and Objectives

The primary objective of our research was to provide answers to key questions about the relationship between alcohol promotions including pricing, level of consumption, alcohol-related harm and the likely social, health and economic costs and benefits of planned or potential policy interventions.

Specifically, our team was commissioned to

- a) systematically review the evidence on the link between the price and promotion of alcohol on the one hand and patterns of consumption and alcohol-related harm on the other as well as the effectiveness of related policy interventions (Phase 1)
- b) indicate how the promotion and pricing of alcohol affects total alcohol intake, and patterns of consumption in groups identified as priorities by government, namely underage drinkers, young adult binge drinkers, heavy drinkers, and those on low incomes (Phase 1) and
- c) model the potential implications of changes to current policies, especially the impact on health, crime, and employment (Phase 2).

In Phase 1, the topic of this first report, we have carried out a systematic review of the evidence base on the relationships between the various types of alcohol promotions, alcohol pricing, alcohol consumption and alcohol-related harm. Where evidence permits, we report separately on different types of alcohol and groups of consumers (including underage drinkers, young adult binge drinkers, heavy drinkers and those on low incomes). Harms are defined widely and include health, social and crime-related harms on individuals and communities.

In Phase 2, based on the findings of the review, available data and current government priorities, we select a number of policy alternatives and model their differential impact on alcohol consumption and alcohol-related harms. Where possible, we model the effects of policy changes on the identified priority groups. The model provides a decision making tool, enabling policy makers to answer what-if questions, to predict the likely downstream impact of different policy scenarios and to identify areas of uncertainty and research priorities for different policy options.

## Background

### UK alcohol consumption and expenditure trends and patterns

The trends and patterns of drinking in the UK are well documented<sup>1</sup> and only a brief summary of the key facts is provided here. HM Revenue and Customs data on alcohol clearances (HMRC 2008) show that overall there has been an increase in per capita consumption of 2 litres of pure alcohol between 1992 and 2004 with smaller fluctuations since then (Fig 1). In 2007/8, the per capita clearance was 11.53 litres of pure alcohol.

In the UK, alcohol consumption is mostly reported in alcohol units. Many other countries use the concept of standard drinks, the alcohol content of which varies by country. Therefore, much of the research literature reported in Review 3 reports uses g or ml of pure alcohol. One UK unit corresponds to 10 ml (or 8g) of ethanol.

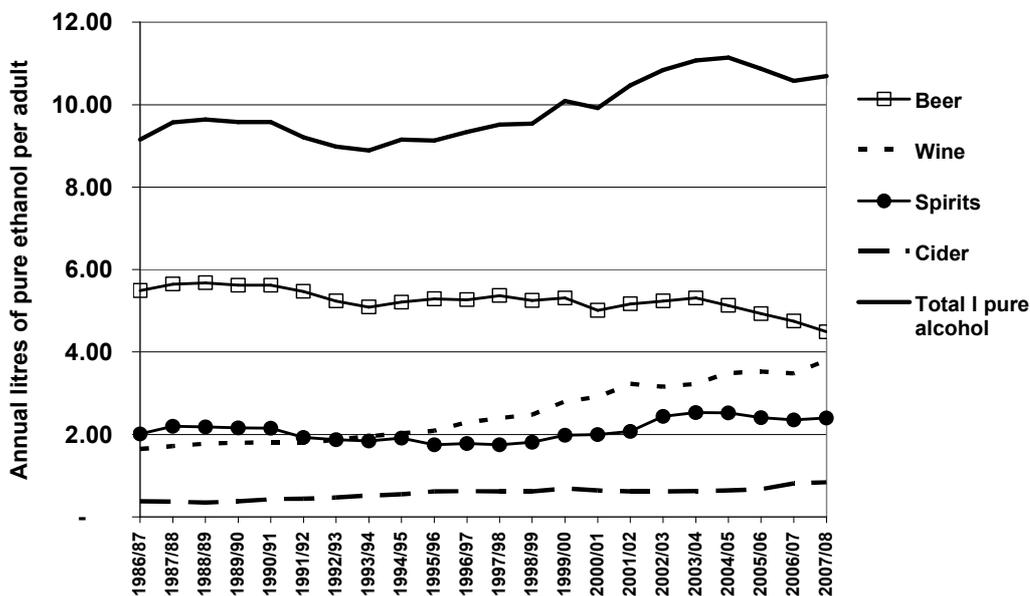

Figure 1. Alcohol clearances 1986/7-2007/8. Source: HMRC 2008.

Based on household survey data, the average weekly amount drunk in 2007 was estimated to be 18.6 units for men and 9.9 units for women when including abstainers, or 23.5 (men) and 14.4 (women) units when looking at those who consumed at least one unit in the past week (General Household Survey 2006 and ONS Omnibus Survey 2007).

The UK government advises that adult men should not regularly drink more than 3-4 units of alcohol a day, and that adult women should not regularly drink more than 2-3 units a day (Department of Health, 2007). In the 2006 GHS, 40% of men and 33% of women reported exceeding the daily limit on at least one day in the past week. The tendency to consume beyond the limit is dependent on age; young people are most likely to exceed recommended limits. In young people, the gender difference in overall levels of consumption is very small, whereas in older age groups, men are clearly the heavier drinkers. GHS data suggests that for the past ten years, the rates of men regularly exceeding the government's recommended daily limits have remained relatively stable, whereas the prevalence of higher-risk drinking in women has been increasing in recent years.

<sup>1</sup> For example, see NHS Information Centre: Statistics on Alcohol 2008 and Association of Public Health Observatories: Indications of Public Health in the English Regions 8: Alcohol, 2007.

Binge drinking is here defined as drinking more than twice the daily recommended allowance, i.e. >8 units per day for men and >6 units for women, in a single session. In the 2006 GHS, 23% of men and 15% of women reported engaging in at least one episode of binge drinking in the past week. Younger age groups were much more likely to binge drink (29% of men and 26% of women aged 16-24). Trends in the prevalence of binge drinking have been largely stable for the past decade. It needs to be borne in mind that because of recollection and social desirability bias, general household surveys are known to substantially underestimate actual levels of drinking, and especially levels of binge drinking (Stockwell et al 2004), thus the above figures are likely to be lower than actual proportion of heavy and binge drinkers in the population.

Harmful drinking is defined, by government, as regularly drinking >50 units per week for men or >35 units for women. In the 2006 GHS, 9% of all men and 7% of all women under the age of 65 reported drinking at this level in the past week, a slight increase since 1998. For those who had had at least one drink in the previous week, the corresponding proportions rose to 12% of men and 9% of women under the age of 65.

In terms of the likely effects of price on heavy drinkers, we were interested to describe how alcohol consumption is distributed in the population. We estimated total annual alcohol intake using GHS 2006 data on weekly consumption, and split the population into deciles according to the level of alcohol intake. Results show that **the top 30% of drinkers consume nearly 80% of the total alcohol volume** (in pure ethanol) consumed in the UK, whilst the bottom 30% of drinkers consume only 2%. Again, it is worth mentioning that problem drinkers are likely to be underrepresented in this general population sample.

In children, the likelihood of ever having tried alcohol is dependent on age, increasing from 21% of 11-year-olds to 82% of 15-year-olds, with few gender differences (SDD, ONS 2006). Asked about past week drinking, which is often used as an indicator of regular drinking, 41% of 15-year-olds had had a drink, compared with 29% of 14-year-olds, 16% of 13-year-olds, and 8% and 3% of 12- and 11-year-olds. Looking at trends, the proportion of children who drank in the past week appears to have increased in the mid-90s, but has decreased since the turn of the millennium. There is however a pronounced trend towards heavier consumption in those who do drink (Fig 2), and the trend is most pronounced in the youngest. 11-13 year old girls reported having drunk an average of 8 units in the past week, and boys of the same age drinking 12 units. At age 15, the level of consumption by those who drink matches and surpasses that of many adult groups (14 units for boys and 11 units for girls).

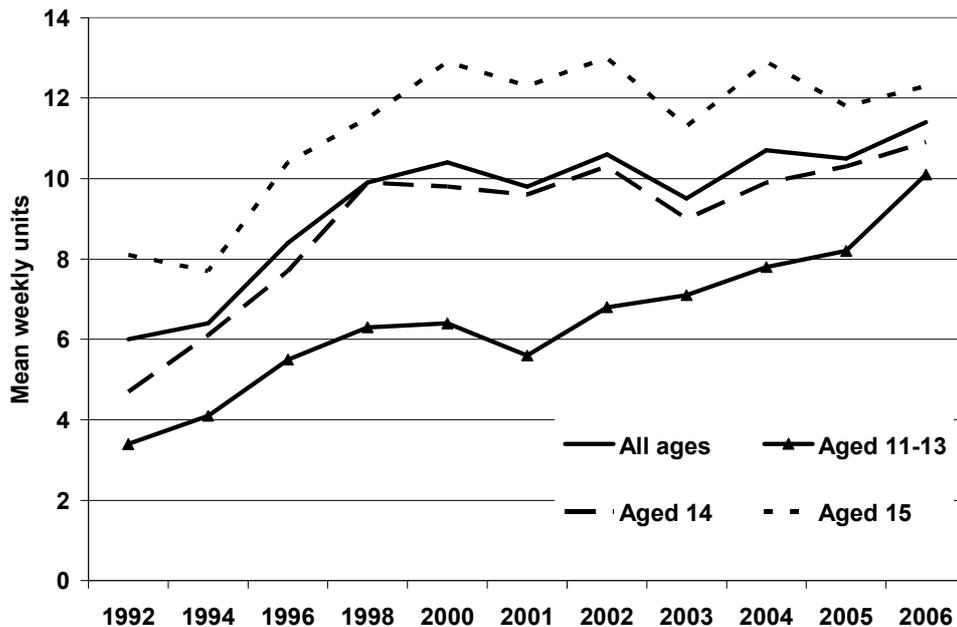

Figure 2. Mean weekly units consumed by 11-15 year olds who have ever had a drink. Source: ONS Statistics on Alcohol 2008.

Data collected in the annual Expenditure and Food Survey (EFS) and its predecessor, the Family Expenditure Survey, allow the examination of trends in the average weekly expenditure on alcoholic drinks. Trends show that expenditure on alcohol rose sharply up to 2003 and increased less sharply since then. Overall, each year individuals spent an extra 10p per week on alcohol than in the previous year, which represents a 4-6% annual rise and is above the average levels of inflation for these years. Slightly more is spent on drinks consumed outside the home (56% of the total expenditure on alcohol). There is a strong linear relationship between income and expenditure for alcohol. Whilst households in the lowest 10% income bracket spend, on average, under £5 per week on alcohol, those in the top 10% income bracket spend over £28 per week.

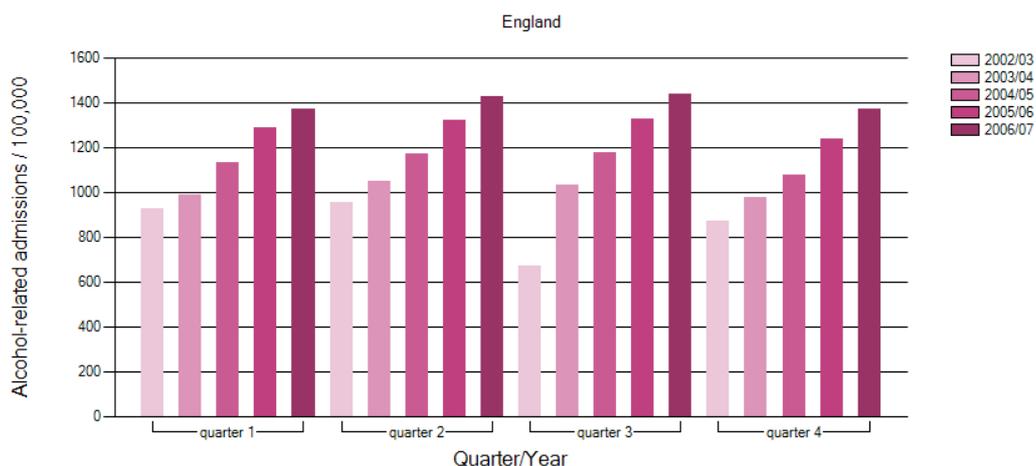

Overall, data show that there has been an upwards trend in both population-level consumption and expenditure on alcohol, that drinking at levels exceeding the government's recommended sensible drinking limits is wide-spread, and that a significant proportion of children drink alcohol and those that do tend to drink increasing amounts.

### Alcohol-related harms

Harms are classified as alcohol-specific or alcohol-related, and can be either chronic or acute. For alcohol-specific harms, all cases of such a disease or harm are directly linked to the consumption of alcohol (for example, alcoholic liver disease, arrests for being drunk and disorderly). For alcohol-related harms, alcohol consumption is a contributory factor in a proportion of cases (for example, certain cancers, road traffic accidents, violent assaults). Chronic harms are those that occur only after a period of sustained alcohol consumption (e.g. alcohol dependence), whereas acute harms are those that are associated with a single occasion of drinking (e.g. road traffic accidents, alcohol poisoning).

A 2003 report on alcohol-related harm estimated the annual cost of health, crime and employment problems caused by alcohol consumption at around £20bn a year (Prime Minister's Strategy Unit, 2003). Since then, trends in alcohol-related harm seem to indicate further increases, and two examples, alcohol-related hospital admissions and alcohol-specific mortality rates, are shown below.

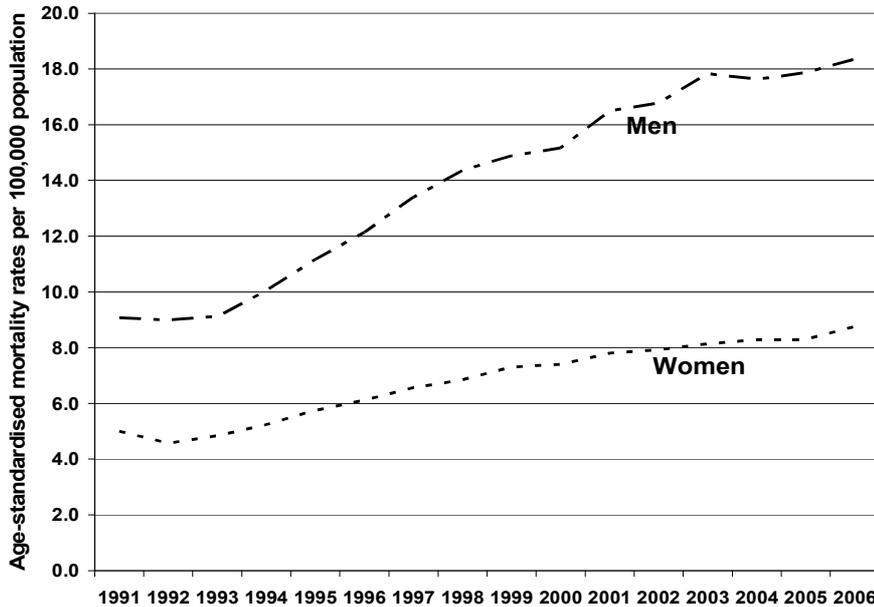

NW Public Health Observatory statistics show alcohol-related hospital admissions are rising by 80,000 admissions a year, with 811,000 admissions (6% of all admissions) in 2006 (Fig 3).

**Figure 3. Quarterly alcohol-related admissions. Source: NWPHO: Local Alcohol Profiles, 2008**

Alcohol-specific mortality rates started rising very sharply between 1993 and 2000, with slower rises after 2004 (Fig 4). The male death rate is substantially higher than the female death rate and the gap is widening – the male death rate has more than tripled since 1980,

the female death rate has doubled. The female death rate is now at just under 8.8 per 100,000 and the male rate is more than double that at 18.3 per 100,000.

**Figure 4. Age-standardised death rates (per 100,000) from alcohol-specific diseases, UK 1991 to 2006: by sex. Source: ONS Death rates from alcohol-related diseases 2008.**

## Trends in alcohol pricing and promotion

### Consumer expenditure

The total annual consumer expenditure on alcohol was estimated to be £42 billions in 2006 (WARC, 2008). In terms of volume of sales, the off-trade<sup>2</sup> market share accounts for 83% of the wine, and 43% of the beer market (BBPA 2007, Mintel, 2007) and in the off-trade, the major supermarkets dominate with almost two-thirds of the market share (AC Nielsen 2008). The off-trade versus on-trade share has been growing steadily for many years (WARC 2008, Mintel, 2007), possibly due to alcohol prices in the off-trade increasing at a rate far lower than the price inflation for most products, whereas prices in the on-trade have increased substantially.

### Alcohol affordability

ONS information<sup>3</sup> is available on alcohol prices compared with the all-items Retail Price Index (here called “alcohol price index”) and real households’ disposable income. From this, an “affordability of alcohol index” can be created, which relates the alcohol price index to income trends. In comparison to 1980, alcohol was 69% more affordable in 2007 (Fig 5). Data is also available, from 1987, on the difference between on-trade and off-trade price developments of wine and beer. Figure 6 shows that whilst on-trade beer and wine were 36% and 46% more affordable in 2007 than 1987, off-trade beer and off-trade wine were 139% and 124% more affordable, respectively.

<sup>2</sup> In the UK, the term off-trade is used to describe alcohol retailing for consumption off the premises (e.g. supermarkets, petrol stations, off-licenses), on-trade is used for alcohol retailing for consumption on the premises (e.g. pubs, clubs, restaurants)

<sup>3</sup> [http://www.statistics.gov.uk/downloads/theme\\_economy/Focus\\_on\\_CPI\\_April\\_2008.pdf](http://www.statistics.gov.uk/downloads/theme_economy/Focus_on_CPI_April_2008.pdf)

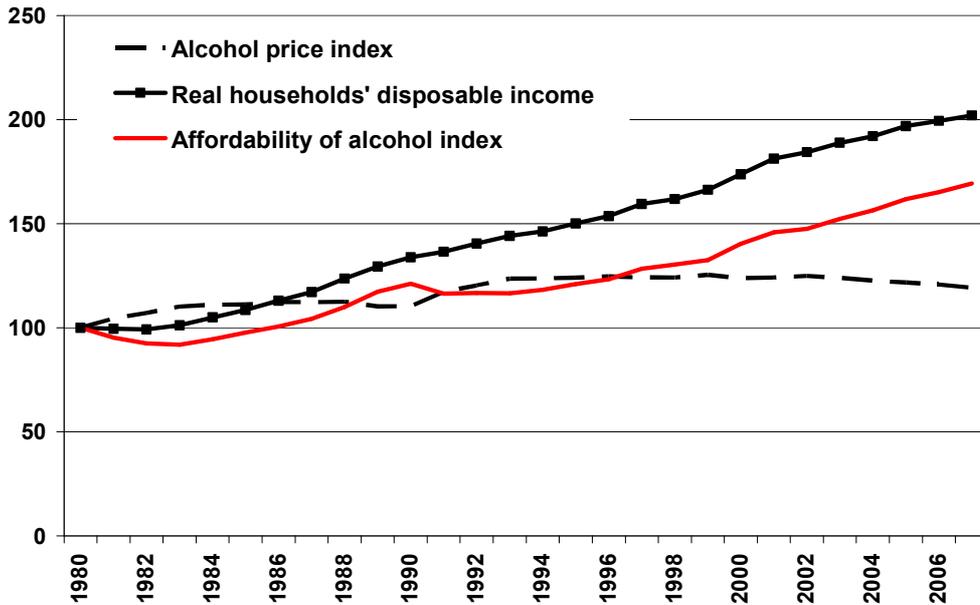

Figure 5. Affordability of alcohol (Source data: Information Centre)

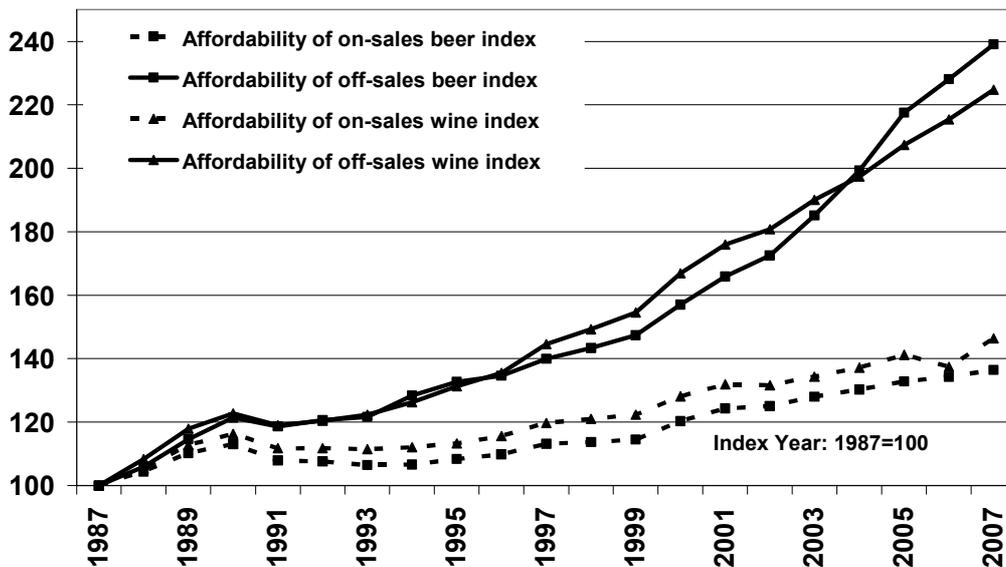

Figure 6. Affordability of alcohol, beer and wine, on-and off-trade comparison

Our account of the marketing of alcohol starts from the fact that it is a behaviour intended by capitalistic organisations to deliver a return to their shareholders. The success of these organisations in generating satisfactory streams of earnings per share helps to make them an attractive investment, and thereby to ensure their continued survival in the market for equity capital. The leading alcohol providers are international conglomerates pursuing ambitious growth strategies. Alcohol marketing activities are designed to maximise international sales turnover and gross contribution.

## **Advertising expenditure**

The total recorded annual advertising expenditure on alcohol was in the region of £163m<sup>4</sup> to £198m (WARC 2007) - these figures include TV, outdoor, press, internet, cinema and direct mail advertising, but not all “below-the-line” expenditures. Of this, almost half (48%) was TV spend, followed by the outdoor (22%) and press (19%) channels. Around half of the annual advertising expenditure is accounted for by beer (48%), followed by ciders (12%) and wine (10%). Overall drinks advertising expenditure rose sharply in the mid-to-late 90s, but has since levelled off. As will be discussed below, advertising is only a proportion of all promotional activity.

## **Marketing and promotion**

The marketing of alcohol is aimed at profitably recruiting and retaining customers. Given corporate growth objectives, there are a number of generic strategies for achieving market growth at the firm level, namely: convert non-users, enter new segments, increase the usage rate of existing customers, and capture market share from competitors. At firm level, investment to improve competitive strength and brand development are also key strategies. Strategies for the marketing of alcohol involve the segmentation of consumers, the targeting of specific groups of consumers and the symbolic and competitive positioning of the organisation’s relevant offering in relation to the target segments – an important consideration for our review’s special interest populations of young drinkers, low income drinkers and regular heavy drinkers. Conventional thinking about marketing strategy has it that these three strategic processes should precede the development of the tactical marketing mix, which includes the product, price, promotion, and place (distribution).

From the marketing point of view, the approach taken in this inquiry is that promotion is a part of marketing strategy, which in turn is part of corporate strategies which aim to achieve corporate objectives, typically increased earnings per share, sales value or volume, market share or some other measure of growth in market/financial return. For the purposes of this inquiry, we have read the word ‘promotion’ to include any kind of communication by alcohol marketers, in line with recent developments in business communications theory.

Alcohol is a product category that is heavily supported by advertising and promotion relative to other categories. The contemporary marketing communications practices and components used by alcohol providers within the UK are wide-ranging and include: any branding practice in general; public relations; corporate communications; TV advertising; radio advertising; print advertising; internet advertising and viral or social e-network marketing; cinema advertising; outdoor advertising; retail sales promotion; trade promotions; direct marketing; personal selling; packaging (multi-pack, design, aesthetics, shape, size); point of sale/point of purchase; merchandise; mobile phone communications; the development of brand identities, brand logos and other aspects of visual identity; product placement; celebrity endorsement; sponsorship; product competitions; event-related marketing; and heritage marketing.

Only a small proportion of these promotional practices and elements are the subject of detailed measurement, and such information tends to be closely guarded due to its sensitive commercial nature. This hampers efforts of academic researchers to evaluate systematically the effects of advertising and promotion, which, as we will see in Review 2, relies heavily on crude indicators such as annual advertising expenditure on selected channels or average TV viewing hours. What research there is will be reviewed in Review 2, however, it needs to be borne in mind that such research will only ever cover a very small proportion of the marketing mix used by the alcohol industry.

## Influences on Alcohol Pricing

Alcohol prices are determined by a range of factors (Huang et al 2003; IAS 2007), including cost to the producer and retailer, strategic decisions about profit margins sought at product and total sales level, levels of taxation (excise duty and value added tax), and the balance between supply and demand.

Apart from indicating the cost to a prospective purchaser, the price of an alcohol product can be regarded as a market signal, which positions the product in terms of value-for-money in the consumer's mind. Pre-purchase, high prices can help to convey an impression of quality, whereas, especially temporarily, low prices may suggest very good value for money in the sense of a bargain. From the provider's point of view, price is a key to optimising the contribution from sales revenue. The relationship between sales volume, fixed and variable costs and revenue stream needs to be managed in the shareholder's interest. Quite apart from this general business requirement, the pricing of alcohol at retail level may be influenced by other factors, such as, for example, intra-organisational pricing strategies, foreign exchange considerations, target return on investment, competitor activity, and category management tactics. That said, two alcohol marketing/pricing strategies have become salient in recent years, namely premiumisation and below-cost selling. Premiumisation involves the prioritisation of certain brands for investment resource allocation, in terms of production, product innovation, marketing spend and distribution. In this strategy, price and promotion are inextricably linked. Higher prices work to signal higher quality, and the promotion aims to confirm this impression to the consumer.

Premiumisation usually leads to a range of different price points for a given product, which suggest different levels of product quality. The strategy is used across a wide range of alcohol drinks, more commonly perhaps in spirits, but including whisky, brandy, champagne and lager.

### Below-Cost Selling

While the international drinks conglomerates are focused on building premium brands, and this tends generally speaking to work well in the on trade, UK supermarket chains (grocery multiples) have a different strategic logic. As the gateway to the consumer, the multiples have long enjoyed significant commercial power in relation to their suppliers. Heavy price discounting or promotion is a key component of their marketing strategy. Below-cost selling is used for a number of reasons, including the protection of category share and the promotion of new products. The danger for drinks brands is the dilution of brand value by heavy retail discounting; one counter-measure is to upgrade products and divert them to more profitable markets at a higher price point.

The Competition Commission recently reported on a range of issues having to do with the practices of grocery multiples (2008). The Commission noted that:

*it was argued by the Royal College of Physicians and others that the widespread availability of cheap alcoholic drinks in grocery stores was encouraging an increase in alcohol consumption, including so-called binge drinking and consumption by those under the legal age limit, leading in turn to violence, disorder and loss of social cohesion.*

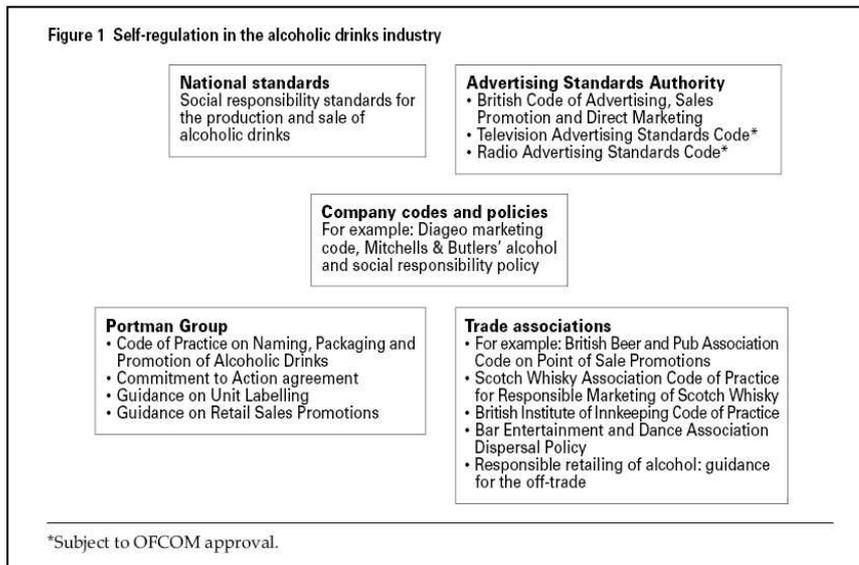

The recent Competition Commission report found in fact that UK grocery multiples were selling a range of categories below cost. Revenue from below-cost selling in general represents about 3% of sales. The CC defines below-cost selling as follows:

*Below-cost selling is where a retailer sells an item to consumers for less than the input cost. For the purposes of our analysis, we have defined a product as being sold below cost if it has a negative gross margin. We calculated gross margin as cash at the till less cost of goods and any adjustment for VAT (where required), and adding back any markdowns (e.g. goods close to sell-by date) and some types of promotional funding (e.g. multi-buys).*

In fact, alcohol was one of the two main categories which were the subject of below-cost selling. It found that: 'The period during which individual products are sold below cost ranges between 8 and 25 weeks. Branded products are generally sold below cost for shorter periods than own-label products'. The period May to July is a peak period for alcohol sales, particularly of multipack offers.

### The current regulatory framework

The following graphic (Figure 7) summarises self-regulation within the UK drinks industry.

**Figure 7. Self-regulation in the alcoholic drinks industry (Joseph Rowntree Foundation 2006, Fig 1, p. 20)**

### Regulatory Authority for Advertising

The Advertising Standards Authority (ASA) is the UK independent regulator that checks advertising code compliance. Non-broadcast advertising is covered by the CAP Code. Broadcast advertising is covered by the Radio Advertising Standards Code, the TV Advertising Standards Code, the Advertising Guidance Notes, Rules on the scheduling of TV advertisements, the Code for Text Services, and the Guidance on Interactive TV. The CAP code is the eleventh edition of the British Code of Advertising, Sales Promotion and Direct Marketing and came into force on 4 March 2003. Its general rules cover issues such as: substantiation, legality, decency, honesty, truthfulness, matters of opinion, fear and distress, safety, violence and anti-social behaviour, political advertising, protection of privacy, testimonials and endorsements, prices, availability of products, guarantees, comparisons with identified competitors and/or their products, denigration and unfair advantage, imitation, recognising marketing communications and identifying marketers, advertisement features and free offers, the protection of children and database practices. A similar range of issues is covered in the broadcast advertising codes.

### Control Processes

The regulation of the promotion of alcohol products operates at a number of levels. The planning and execution of alcohol promotional campaigns is subject to various control mechanisms. Firstly, in the course of campaign planning, the firm will discuss the issue of code compliance with its marketing communications agency. Secondly, compliance may also be checked within an individual firm. Thirdly, within the UK, a proposed advertising campaign may be referred to the Portman Group for a view on its compliance. Fourthly, the Advertising Standards Authority regulates the promotion of alcohol across a number of media. The ERDF

(European Responsible Drinking Federation) is an umbrella industry body, which publishes reports on compliance.

## Systematic Reviews

## Background to the reviews

The research question was conceived in three separate and yet connected parts:

1. Investigating the relationship between **Tax/Price** and **Alcohol Consumption** or directly to **Harm [Review 1]**
2. Investigating the relationship between **Advertising/Promotion** and **Alcohol Consumption** or directly to **Harm [Review 2]**
3. Investigating the relation between **Alcohol Consumption** and **Outcomes**. Outcomes include either health and health service-related outcomes (e.g. those relating to chronic disease, traffic accidents) or societal outcomes (e.g. those relating to crime or employment) **[Review 3]**. Neither Review 3 nor the subsequent modelling work is required to extend to include beneficial effects in terms of individual “feel good” factors or general quality of life. However the evidence for supposed health benefits such as cardioprotection and reduced risk of stroke is examined.

These reviews were conceived as three separate analyses each requiring a different type of evidence base and engaging with different bodies of literature. Methodological challenges posed by different types of evidence and issues of causation and direction of influence are discussed in detail at the end of this methodology section.

## Methodology

A review was undertaken according to systematic review principles. The methodology used closely followed the review framework described in the NHS Centre for Reviews and Dissemination (CRD) Report No. 4, *Undertaking Systematic Reviews of Research on Effectiveness* (Khan et al, 2001). For Review 3 on the relationship between alcohol consumption and outcomes, a review of reviews was undertaken. According to the Government Social Research Unit<sup>5</sup> a review of reviews is appropriate where there has already been considerable research and a number of research reviews undertaken in a particular area. The limitation is that it will obviously not pick up research outside of existing reviews. Also, as reviews are of variable quality each individual review needs to be screened to assess how systematic and comprehensive it is. The review of reviews shares the systematic approach with other systematic review methods. It has the advantage of generally being quicker than other types of full systematic review.

## Search strategy

### Sources

Multiple methods were used to identify relevant literature. Sensitive search strategies were employed in searching the following major electronic bibliographic databases and resources:

### Health

- Medline
- Medline In-Process
- Cochrane Database of Systematic Reviews
- Cochrane Central Register of Controlled Trials
- Database of Abstracts of Reviews of Effects (DARE)
- Health Technology Assessment (HTA)
- NHS Health Scotland

### Health-related

### **Retrieval of 'grey' literature**

Grey literature, including evaluations and empirical studies, reviews and guidance documents, has been retrieved from targeted Internet searches, from the websites of organisations judged to be relevant to the review and from in-house files. Contact with experts was also used to obtain unpublished and imminently published materials. Most of the grey literature was used for background and contextual purposes with the majority of research studies being identified from the bibliographic subject searches and from follow up of reference lists

### **Search terms**

A combined free-text and thesaurus approach was adopted. Search terms included: "alcohol drinking", "alcoholic beverages", "campaign\$", "promot\$", "advert\$", "publicity", "market\$", "pric\$", "tax". The search was limited to English language only and to research or systematic reviews published after 2000 to ensure currency and applicability of the research. An example of the search strategy used is found in Appendix 1.

In addition, a specific search was conducted to identify reviews on the harmful effects of alcohol. This search was limited to English language only, research and systematic reviews published after 2000. A full search strategy can be found in Appendix 2.

### **Inclusion Criteria**

#### **Types of studies**

- 1) Systematic review
- 2) Research study
- 3) Data analysis – studies reporting quantitative data from routine or ad hoc datasets regardless of whether or not they have an empirical base.
- 4) Economic study – in the broadest sense to include cost studies as well as economic evaluations.

### **Types of participants**

Studies were not limited to specific types of participants; however additional analyses were carried out to examine findings for the following policy priority groups:

- underage drinkers (persons under the age of 18),
- young adult binge drinkers (persons aged 18-25, drinking more than the equivalent of 6 UK units (women)/8 UK units (men) on a single occasion)<sup>6</sup>
- harmful drinkers (persons regularly drinking more than the equivalent of 35 UK units per week for women/50 UK units per week for men)<sup>7</sup>, and
- those on low incomes

### **Types of intervention(s)/exposure(s)**

The following interventions/exposures were included:

#### **Price:**

- Tax increase(s)
- Tax decrease(s)
- Price increase(s)
- Price decrease(s)

#### **Policy:**

- Change in coverage of tax policies
- Policies with a direct effect on pricing (e.g. minimum pricing)

#### **Promotion:**

- Advertising interventions
- Promotion interventions

### *Exclusions*

Of 10 policy options identified as 'best practices' by Babor et al (2003) the following are excluded from the scope of this review:

minimum legal purchase age, government monopoly of retail sales, restrictions on hours or days of sale, outlet density restrictions, sobriety checkpoints, lowered BAC limits, administrative licence suspension, graduated licensing for novice drivers and brief interventions for hazardous drinkers.

### **Types of outcome measure(s)**

#### **Consumption:**

- Decrease in consumption
- Increase in consumption
- Increased Intention for purchase
- Increased Intention for consumption
- Substitution of one type of alcohol for another
- Substitution of alcohol for another product
- Substitution of another product for alcohol

#### **Health:**

- Harmful effects on health
- Health benefit

#### **Social:**

---

<sup>6</sup> It is important to note that the literature reflects a wide range of international definitions of "binge drinking" This review consistently focuses on the accepted definition for the United Kingdom as given above.

<sup>7</sup> Throughout the main report and accompanying summary the review team uses the terminology "harmful drinkers" consistently to represent this category. However where study authors use different terminology e.g. "heavy drinkers" we preserve the original usage by the authors.

- Social harm, including teenage pregnancy, crime, detrimental effects on social cohesion
- Social benefit, including potential positive effects on social capital
- Increased awareness of alcohol advertising

**Economic:**

- Economic harm
- Economic benefit
- Price elasticity

**Methodological quality**

The main challenge, as in virtually all studies on policy effects, is to seek to establish a causal link between a change in pricing and/or promotion and the subsequent observations regarding consumption and/or harm. Bradford Hill's principles were used as an aid for examining causation (Macdonald et al, 2005). However, this was to facilitate the quality assessment process rather than to disqualify other types of studies that exist across a wide spectrum of designs and types.

To establish causation one needs to start by trying to establish that the intervention predates the effect (**temporality**). This can be difficult where authors have attempted to correlated two variables in a cross-sectional study design, but the temporality criterion is met in longitudinal, panel and time series analyses. This is the case for econometric studies and the natural experiments described in the review).

Economic theory provides a plausible explanation for how price and promotion changes affect demand (**plausibility**), assuming that such complexities as substitution (of a cheaper and potentially more harmful variant of the product) or cross-product migration (either to other forms of alcohol or to other products such as cigarettes or recreational drugs) are factored into the overall picture. Plausibility also involves the absence of alternative, more plausible, explanations for the observed effects.

Assessments of causal inference also need to consider the **consistency**. This relates to a) the number of studies finding an effect compared with studies reporting no effect or opposite effects, b) the degree to which studies using different designs and methods come to the same conclusion) and c) the degree to which findings can be replicated in different populations and settings. The higher the proportion of studies that point in the same direction, no matter which design and method is used or in which setting they are carried out, the higher the likelihood of a causal relationship.

A further consideration is the **strength** of effects found (the stronger the effect, the more likely it is that there is a direct causal link between two variables).

In addition, there is a criterion of "**biological gradient**" or **dose-response** (i.e. one would expect that, all other things being equal, large price increases would lead to greater reductions in consumption and harm than small ones). If a dose-response relationship is observed, this is considered strong evidence for a causal relationship. However, the absence of a dose-response relationship does not negate a causal relationship, as studies may be covering a too narrow range of observations and encounter a "threshold effect" beyond which no further increases or decreases occur. This may be relevant in particular for the review of advertising effects in the econometric literature. In most developed countries alcohol advertising is highly pervasive and a slight increase or decrease in advertising expenditure may not result in noticeable differences in consumption or harm. In such cases, studies on step-changes, such as complete bans, deliver stronger indications of causal relationships.

A final important criterion is **experiment**. The ideal study type here is the true experiment, with controlled conditions, which allows the highest degree of confidence in establishing causality. However, this type of study is rarely feasible in policy research, especially where population-level policies are concerned. The ways in which this is typically overcome include to choose study designs that reduce bias. The strongest evidence in the field comes from studies which are designed to adequately control for confounders (for example, increases in

personal disposable income) and which examine co-variation over time (as prices increase, consumption decreases and as prices decrease, consumption increases).

There are a number of minor criteria. **Specificity** is often considered the weakest of the listed criteria. Specificity is established when a single putative cause produces a specific effect. However, it is now accepted that most behavioural and disease outcomes (in our case, consumption and harm) are likely to have multiple determinant factors and so it is highly unlikely that there would be one-to-one cause-effect relationship between any of the phenomena under consideration. When specificity of an association is found, it provides additional support for a causal relationship, but its absence does not rule out a causal relationship. **Coherence** considers the degree to which an association fits with existing theory and knowledge. One would demand a higher level of confidence with regard to all other criteria if an assumed new link between two variables contravened what is considered established knowledge. This could for example apply if the review found that the economics of alcohol demand were different to those of other comparable commodities. The **Analogy** criterion is similar in that it asks for an evaluation whether known effects in an analogous area can be transferred to the current area. For example, if it was well-established that children react more strongly to tobacco, sweets and soft drinks advertising compared with adults, this adds weight to a causal interpretation if a similar observation is made for alcoholic drinks.

These methodological considerations should thus be borne in mind when considering the evidence that follows.

## Review 1: The effect of pricing and taxation on alcohol consumption

### 1.1 Introduction

In their comprehensive international review, Babor et al (2003) observed that “the regulation of alcohol taxes and prices has been by far the most popular” strategy used to control alcohol related problems. Among the claimed advantages are the generation of governmental income, the relative ease of implementation through legislation and the ease of enforcement.

Babor et al (2003) concluded that: “Economic studies conducted in many developed and some developing regions of the world have demonstrated that increased alcoholic beverage taxes and prices are related to reductions in alcohol use and related problems”.

The evidence base for the effect of pricing and taxation comprises two principal sources:

1. Econometric studies that look at co-existing trends between price and consumption or between price and harm.
2. Natural experiments where opportunistic monitoring of changes to alcohol pricing or taxation in a particular country or jurisdiction has identified subsequent changes to patterns of consumption and/or harm. Evidence from these studies is strongest where they are able to report on control jurisdictions, ideally in the same country, where prices/taxes have not changed.

#### 1.1.1 Structure of this review

This review begins by considering studies that link **pricing or taxation to consumption** (Section 1.2), including a small section on minimum pricing policies (1.2.1). It then proceeds to examine studies on the effects of changes in **pricing or taxation on harm** (Section 1.3). Section 1.4 examines the **implications for particular policy priority groups**, followed by a summary of review findings (1.5.).

#### 1.1.2 Summary of quantities of evidence by topic

This review attempts to include both significant primary studies and the results of systematic reviews. The following table reports the respective yield for the major topics covered by this review.

**Table 1. Number of included and covered studies**

| <i>Section</i>                  | <i>Number of studies included</i>   | <i>Number of studies covered<sup>8</sup></i> |
|---------------------------------|-------------------------------------|--|
| Pricing/Taxation to Consumption | Gallet meta-analysis (2007)         | 132  |
|                                 | Wagenaar et al meta-analysis (2008) | 91   |
|                                 | 15 other studies                    | 15   |
| Taxation/Pricing to Harm        | 46                                  | 46   |

<sup>8</sup> This includes studies accessed via the results of large meta-analyses or studies that, due to logistic constraints or agreed limitations of the scope of this review (e.g. date, language), are not included in the accompanying evidence tables (See Appendix 3).

## 1.2 Alcohol prices or taxation and the consumption of alcoholic beverages

The impact of price changes on alcohol consumption has been more extensively investigated than any other potential alcohol policy measure. Frequently such studies take the form of econometric studies examining price elasticity in connection with demand or consumption. The term elasticity is used in econometric studies to measure how much demand for alcohol or alcohol-related harm changes when the price of alcohol changes. A product is described as **price elastic** when the percentage change in demand is greater than the percent change in price. A product is described as **price inelastic** when the percentage change in the amount of demand is less than the percent change in price. All of the following studies consider the relationship between price and alcohol consumption. Two major systematic reviews of price elasticities have been identified by this review.

Gallet (2007) has conducted a meta-analysis of 132 studies reporting elasticities. His meta-analysis is of reasonable quality and is certainly superior to any such analysis possible within the time and resource constraints of these reviews. Gallet's data is therefore used below with special emphasis given to any studies conducted in a UK setting or to those completed subsequent to his data collection.

A new and highly comprehensive meta-analysis has been recently conducted by Wagenaar et al (2008). This review systematically searched nine major scholarly databases of published research material covering health, social, behavioural and economic disciplines for relevant studies enabling numeric estimates to be made of the relationship between price changes and changes in the consumption of alcohol. Inclusion criteria were met by 91 individual studies that cover the relationship between either pricing or taxation and alcohol consumption.

### Details of studies

132 studies are included in Gallet's (2007) meta-analysis. All studies were published in English, with the earliest being published in 1945 and the most recent in 2003. The majority of studies were conducted in the USA. An initial search of Econlit was supported by follow up of references from traditional narrative reviews and from included studies and supplemented by internet searches. Price elasticity values were used as the units of analysis. Identification of UK only studies is reported in Appendix 1.

In addition to those included in the meta-analyses, 15 further studies met the inclusion criteria. All studies were published in English, with the earliest being published in 1993. The majority of studies (n=7) were conducted in the USA. Only one study was based specifically in the UK.

### Outcomes

Studies measured price elasticity using a variety of methods for specifying alcohol demand. 1172 estimated price elasticities are reported. Most studies examined both own-price and cross-price elasticities.

### Results

The price-elasticities for alcoholic beverages estimated in different studies have shown that when other factors remain unchanged, an increase in price has generally led to a decrease in alcohol consumption, and that a decrease in price has usually led to an increase in alcohol consumption, with the size of the elasticities sometimes dependent on the relative presence or absence of other alcohol policy measures (Farrell et al. 2003; Trolldal and Ponicki 2005).

Gallet (2007) reports median price elasticities for Beer (-0.36); Wine (-0.700); Spirits (-0.679) and Alcohol (-0.497). An analysis of annual data from Australia, Canada, Finland, New Zealand, Norway, Sweden, and the United Kingdom from the mid 1950's to the mid 1980's found price elasticities of -0.35 for beer, -0.68 for wine, and -0.98 for spirits (Clements et al. 1997). This means that if the price of beer is raised by 10%, beer consumption would fall by 3.5%; if the price of wine was increased by 10%, wine consumption would fall by 6.8%; and if the price of spirits increased by 10%, spirits consumption would fall by 9.8%. Whilst reported price elasticities are consistently negative, there are differences between countries and within

countries over time, as to the degree to which alcohol consumers react to changes in the price of alcoholic beverages. Even within a given country there may be a significant diversity of price elasticity values cited across studies (Österberg 1995; Chaloupka, Grossman and Saffer 2002). Reviews of demand models from 1989 and 1990 in the United Kingdom found that the demand for beer, wine, and spirits was generally price-inelastic, with the demand for wines and distilled spirits being more responsive to prices than the demand for beer (Godfrey 1989 1990). More recent estimates found price elasticities of -0.48 for beer consumed on premises, -1.03 for beer purchased and consumed off premises, -0.75 for wine, and -1.31 for spirits (Huang 2003).

The standard economic assumption in such studies is that tax changes were passed on to the consumer in equivalent of price changes. This is a conservative estimate as empirical work suggests that a 10% tax increase will usually generate a price increase of between 10 and 20% (Kenkel, 2005; Young and Bielinska-Kwapisz, 2002). Among the 91 studies included in Wagenaar (2008), 74 found a significant negative relationship between taxation or prices and consumption with an overall elasticity estimate of -0.51. Mean elasticities for specific beverages were -0.46 for beer (105 studies), -0.69 for wine (93 studies) and -0.80 for spirits (103 studies). The meta-analysis found significant relationships ( $p < .001$ ) between alcohol tax or price measures and indices of sales or consumption of alcohol ( $r = -0.17$  for beer,  $-0.30$  for wine,  $-0.29$  for spirits, and  $-0.44$  for total alcohol). Significant effects were also found for alcohol prices on heavy drinking, although the effect sizes were smaller than for overall drinking (Wagenaar et al, 2008). Wagenaar's estimates are quite similar to those from another recently published analysis (Gallet, 2007) who reported median price elasticities for wine (-0.70), spirits (-0.68) and all alcoholic beverages (-0.50), but a slightly higher elasticity for beer (-0.36). The latter study included over 1000 estimates from studies conducted since 1945.

Natural experiments have demonstrated that increases or decreases in price are likely to be associated with sharp decreases or increases respectively in per capita alcohol consumption (Bruun et al, 1975; Cook 1981; Cook & Moore 1993; Chaloupka et al 1993; Godfrey 1997). For example a study from New Zealand by Zhang and Casswell (1999) found beer consumption declined with an increase in real price during the early 1990s. Conversely an increase in wine consumption during the same period was partly attributable to a decrease in the real price of wine.

Another natural experiment occurred in Switzerland with its reform of spirits taxes, which came into effect on 1 July 1999. Previously, the tax rate per litre of pure alcohol for domestic spirits was Swiss francs 26.00 and for foreign spirits between Swiss francs 32.00 and 58.00, according to the type of beverage and its alcohol content. The fiscal reform also liberalized the import of spirits. The result was a reduction of between 30% and 50% in the retail price of foreign spirits. Prices of domestic spirits, however, did not change. Spirits consumption increased significantly (by 28.6%) in the total sample, and specifically in young males and in individuals who were low-volume drinkers at baseline (Heeb et al. 2003). Consumption of alcohol overall, or of wine or beer, did not change significantly. No indication of effects of substitution was found. Alcohol-related problems also increased significantly; an effect that disappeared when spirits consumption was controlled for. This suggests that the increase in alcohol-related problems at follow-up was directly associated with increased consumption of spirits.

Kuo et al (2003) demonstrates that younger people are particularly likely to be affected by price and several other studies show that the price of beer is a significant factor when targeting young people, especially young males.

Changes in alcohol consumption are not only determined by changes in price, but also by changes in income. Therefore, measures that ensure that taxation or pricing increases match or exceed that of rises in personal disposable income (Laixuthai & Chaloupka, 1993) can be expected to be more effective.

### Limitations

Individual authors have argued that to some degree, levels of taxation may reflect the characteristics of the wider environment. In a cross-sectional study, Dee (1999) explored variables other than price (such as anti-alcohol sentiment) as an explanation for effects of varying alcohol taxes. Having taken this potential confounding variable into account, the effect of taxes on drinking levels disappeared, leading the author to the conclusion that taxation may therefore simply reflect the presence of an anti-alcohol environment. However, taxation changes are typically prompted by economic rather than public health considerations, and Dee's study cannot explain findings of many natural experiments of tax changes in the same country, where it is highly unlikely that an "overnight change" of anti-alcohol sentiment has taken place.

### Summary

Collectively, these studies span dozens of countries and many decades of experience of the relationship between alcohol prices and consumption. The effects of price changes on alcohol consumption are significant and of a substantially larger size than other alcohol policy interventions (Babor et al, 2003). There is, however, substantial variation in the size of the relationship, although it is consistently negative, i.e. in the direction of reduced consumption as prices increase. Estimates of price elasticities vary by beverage type, country, population group (e.g. age of consumer) and quality of product (Stockwell and Gruenewald, 2003). This should not be surprising as "alcohol" is not one product. Alcohol markets in developed countries typically include many thousands of different products arranged upon a spectrum of price and quality (Ponicki et al 1997, Stockwell and Crosbie, 2001).

Drinkers who have access to a large supply of cheap alcohol are likely to drink both more regularly and to consume a greater amount of alcohol overall (Chaloupka et al, 2002). Consistent with this, studies have reported that increasing the price of alcohol reduces heavy drinking (Coate and Grossman 1988; Kenkel 1993 1996; Manning et al. 1995), as well as alcohol dependence (Farrell et al. 2003).

There is strong evidence that hazardous drinkers tend to choose cheaper drinks, whether they are young binge drinkers (Wechsler et al, 2000) or problem drinkers (Stockwell, 2000). In addition in most developed countries approximately 20% of drinkers consume approximately 80% of all alcohol sold (e.g. Stockwell et al, Personal Communication) and this has been shown to be similar in the UK using data from the English General Household Survey (see Introduction). Influencing the prices of the cheapest drinks on the market by raising "floor prices" has a larger impact on total consumption than does increasing the prices of more expensive drinks (Gruenewald, 2000). Using the empirical results obtained in their study of the Swedish alcohol monopoly from 1984 to 1993, the authors predicted the impact of a 10% increase in average beverage prices on sales under three scenarios: a flat price increase across \*all beverages\* led to a 1.7% drop in sales, a price increase affecting mainly \*higher quality beverages\* led to a 2.8% increase in sales, and a price increase affecting \*lower quality beverages\* led to a 4.2% drop in alcohol sales (Gruenewald & Treno 2000). For public health and safety purposes, it is therefore important to think about the structuring of alcohol taxes across all alcoholic products and not just average tax rates.

In terms of the policy priority groups, studies have found that increases in the price of alcohol reduce the alcohol consumption of young people, with a greater impact on more frequent and heavier drinkers than on less frequent and lighter drinkers (Laixuthai and Chaloupka 1993; Chaloupka and Wechsler 1996; Cook and Moore 2002). Beyond levels of drinking, price has also been found to influence drinking to intoxication, which is associated with the highest levels of acute harm. One large survey in the USA found that a 10% increase in price would decrease the number of intoxication episodes per month by 8% (defined as consuming 5+ drinks on one occasion; Sloan et al. 1995).

**Evidence statement 1: There is strong and consistent evidence to suggest that price increases (including through taxation) have a significant effect in reducing demand for alcohol. The evidence base is derived from studies from four different countries (USA,**

**Australia, Switzerland and the UK) and uses a variety of study designs and methodologies.**

**Evidence statement 2: There is strong evidence to suggest that young drinkers, binge drinkers and harmful drinkers tend to choose cheaper drinks. Low income groups have not been studied specifically.**

### **1.2.1 Minimum pricing**

Increasingly retailers such as supermarkets use discounting of alcohol products at low prices, or even below cost, to attract customers to buy other more profitable goods. While such staples as bread have been used in this way for many years there is growing concern that this is being used extensively for alcohol which is an addictive good with known harmful health and social consequences. Minimum pricing policies attempt to counter practices “in which retailers set very low prices, sometimes below cost, for some products to lure customers into stores” (Hess and Gerstner, 1987). Loss leaders are typically heavily advertised.

#### **Details of studies**

In countries where central governmental control does not restrict minimum pricing, local restrictions have sometimes been used to exercise this control on the sale of very cheap beverages (e.g. where cheap wines caused substantial problems in rural Australian communities with a high Aboriginal population, Gray et al, 2000).

#### **Results**

In an evaluation of the Tennant Creek (Aus.) initiative Gray and colleagues (2000) found that over the two years following the introduction of such the restrictions, there was a reduction of 19.4% in annual per capita consumption of pure alcohol. This was accompanied by declines in hospital admissions for acute alcohol-related diagnostic related groups; and persons taken into police custody and the proportions of offences reported on Thursdays, when government subsistence payments were paid. Furthermore, most survey respondents favoured retention or strengthening the existing restrictions.

#### **Limitations**

Some critics argue that from an economic point of view minimum pricing may have a reverse effect than that which is desired, i.e. that by guaranteeing an expected price, manufacturers may be provided with an incentive for increased production. This argument is unlikely to be true, since it is demand that drives production of products at a certain price. From a public health viewpoint, however, a minimum pricing policy appears to make sense by reducing consumption (within elasticities discussed above) and thus reducing the harmful health and social consequences.

#### **Summary**

Gray and colleagues conclude that minimum pricing strategies may constitute an effective part of a broad public health strategy to deal with alcohol-related problems. There is also evidence, reviewed below, that heavy and problem drinkers are more likely to select cheaper alcohol products - it follows that raising floor prices will have a disproportionate effect on those drinkers at most risk of harm.

**Evidence statement 3: There is low quality but demonstrable specific evidence to suggest that minimum pricing might be effective as a targeted public health policy in reducing consumption of cheap drinks. There is also evidence to suggest that such a policy may be acceptable to many members of the community. Further research is required to validate these findings for UK populations and for policy priority groups.**

### **1.3 Taxation or pricing studies linked to harm**

Although conceptually there is a difference between taxation increases (where revenue is directed to the taxation authority) and price increases (where additional income may be

channelled in the form of additional profits to the producer) there is an overlapping evidence base in that the putative mechanism of deterrence (and hence harm reduction) is common to both. This set of studies attempts either to establish a link between changes in taxation and subsequent changes in alcohol-attributable harm or between changes in pricing and subsequent changes in harm. A narrative synthesis is preferred here because of the heterogeneity of studies in this sample. However, for ease of identification the tables for the two sets of studies are kept separate. No systematic reviews of the effects on harm of either taxation or pricing changes were found.

### **Details of studies**

24 studies met the inclusion criteria for taxation studies. All studies were published in English, with the earliest being published in 1993. The majority of the studies were conducted in the USA. No studies exclusively examined policy priority groups although several studies included subsets of data examining impact on binge drinkers or harmful drinkers.

22 studies met the inclusion criteria for pricing studies. All studies were published in English, with the earliest being published in 1998. A large majority of studies were conducted in the USA. While most of the studies examined effects on the general population several looked for effects on heavier drinkers. In addition some of the outcome measures (e.g. number of traffic accidents) were chosen because they possess a high alcohol-attributable fraction and therefore are more likely to reflect the behaviours of at risk groups.

### **Outcomes**

Outcomes varied according to the exposure of interest e.g. sexually transmitted diseases were determined by incidence rates and traffic accidents by fatality rates. Outcomes also included robbery, assault and sexual assault, and injuries.

### **Results**

There is a clear indication for a link between tax and the harm attributable to alcohol in the majority of identified studies. Chisholm et al (2004) remark that, on the basis of their modelling, in a population with a higher prevalence of heavy drinkers (i.e. more than 5% as is the case in Britain) the most effective and cost-effective intervention was taxation whereas in populations with a lower prevalence advertising bans are more effective than taxation, although the underlying evidence base for this observation does not appear strong.

Increasing the price of alcohol and beer reduces road traffic accidents and fatalities among people of all ages, but particularly for younger drivers (Kenkel 1993; Ruhm 1996 Chaloupka and Laixuthai 1997 Dee 1999; Mast et al. 1999; Dee and Evans 2001; Chaloupka et al. 2002 Saffer and Chaloupka 1989; Evans et al. 1991; Chaloupka et al. 1993; Sloan et al. 1994a; Mullahy and Sindelar 1994a). On the basis of such studies, it has been estimated that a policy adjusting the USA beer tax for the inflation rate since 1951 to the mid-1980s would have reduced total road traffic fatalities by 11.5 percent and fatalities among 18- to 20-year-olds by 32.1 percent (Chaloupka et al. 1993).

Increases in alcohol prices reduce cirrhosis death rates (Grossman 1993; Cook and Tauchen 1982), intentional and unintentional injuries (Sloan et al. 1994; Grossman and Markowitz 1999), workplace injuries (Ohsfeldt and Morrisey 1997) and sexually transmitted disease rates (Chesson et al. 2000).

Higher beer prices have been shown to lead to reductions in rapes and robberies (Cook and Moore 1993), homicides (Sloan et al. 1994), crime (Saffer 2001), child abuse (Markowitz and Grossman 1998; Markowitz and Grossman 2000), wife abuse (Markowitz 2000), violence at universities (Grossman and Markowitz 2001), and violence-related injuries (Matthews et al. 2005).

In the United Kingdom, it has been estimated that a 10% rise in the prices of alcoholic beverages would lead to a drop of 7.0% in male and 8.3% in female cirrhosis mortality, a drop of 5.0% for male victims and 7.1% for female victims of homicide, and a drop of 28.8% for male and 37.4% for female deaths from explicitly alcohol-involved causes (alcohol dependence, poisoning, etc.) (Academy of Medical Sciences 2004).

Numerous studies investigate whether there are direct effects of changes in price and/or taxation on indices of alcohol-related harm. While it is assumed that those effects which are found are due to mediating effects on volume or pattern (including location) of alcohol consumption, the outcome variable of most interest in these studies tends to be alcohol-related harms such as rates of liver cirrhosis, road trauma or sexually transmitted disease.

An Australian study evaluated the public health impact of a rare policy event: an increase in alcohol taxes in one jurisdiction which was later reversed (Chikritzhs et al, 2005). It was found that an increase in tax on drinks with an alcohol content above 3% alcohol by volume in the Northern Territory in 1992 significantly reduced acute but not chronic alcohol caused mortality in comparison with adjacent areas of Western Australia and Queensland. Other international studies have also found associations between tax changes and harms including: acute deaths in Finland (Koski et al, 2007), small effects on deaths from all causes in the USA (Cook et al, 2005), male suicides in the USA (Markowitz et al, 2003), assaults in the USA (Markowitz et al, 2005), male sexually transmitted diseases (Carpenter, 2005) and unwanted pregnancies (Sen et al, 2003).

### **Limitations**

These studies are valuable as they examine the link likely to be most useful for decision-makers i.e. between the policy or pricing decision and subsequent harm. Many of these studies describe associations between alcohol prices and harm variables using time series data, but not all include comparisons with control states/jurisdictions where changes have not been implemented or control for confounders. Some of the strongest studies include multiple jurisdictions in the same country which permit comparisons of different tax and price levels for alcohol beverages in an otherwise very similar setting, and which varied to differing degrees over the periods studied. One such example is a study concerning the impacts of alcohol tax changes and minimum age purchase laws on road trauma across 48 USA states, finding significant negative associations suggesting increased prices reduce alcohol-related road trauma (Ponicki et al, 2007).

### **Summary**

Most studies examine correlations between two independent datasets - those measuring the exposure (alcohol taxation or alcohol pricing) and those measuring the putative outcome (harm). There is a need to differentiate between acute and chronic harms, where one would expect immediate effects on acute harms such as from drink driving. There is some discussion about the importance of time lags for chronic harms (e.g. liver disease), but the preponderance of evidence points to both immediate and somewhat delayed effects.

**Evidence statement 4: A large number of studies consistently suggest evidence for an association between increases in taxation or pricing of alcohol and reductions in harm.**

## **1.4 Implications for particular policy priority groups**

### **Underage drinkers**

It is suggested in the literature that youth may be especially sensitive to price because they often have little money of their own, and those who drink heavily may not yet be addicted or may not be so addicted that they become less responsive to price changes. A recent UK study found a strong relationship between teenagers' disposable income and their likelihood of binge drinking (Bellis et al 2007).

Laixuthai and Chaloupka (1993) found that raising beer prices through taxation would cut both the overall number of young drinkers and the number of those who drink heavily. Higher beer prices were found to significantly reduce the likelihood for drinking, drinking frequency and binge drinking in underage and adult female drinkers (but not male drinkers, Chaloupka & Wechsler, 1996).

### **Binge drinkers aged 18-24**

As with others of our interest groups young binge drinkers tend to choose cheaper drinks (Wechsler et al, 2000). One study found that modest increases in levels of taxes have no effect on the number of drinks consumed or on binge drinking (6 or more drinks on one occasion) (Gius, 2002) but as this was in an over 29 age group it is problematic to extrapolate to a markedly younger population. Furthermore this was an isolated finding and certainly conflicts with much of the evidence identified for this review. Chaloupka and Wechsler (1996) used a questionnaire approach to explore likely reactions to a tenfold increase in the tax on beer and found it would reduce binge drinking by young women by about 20%, but would have no effect on young men. However the researchers attributed the small impact on women and lack of effect on men to measurement error. A substantial tax increase is thus required to achieve modest reductions in binge drinking by female students (Chaloupka and Wechsler, 1996). Keng & Huffman 2007 found that binge drinking by young people is highly responsive to state taxes on alcohol. They conclude that an increase in local alcohol price decreases the occasions of binge drinking, and thus the individual is less likely to become a binge drinker (Keng & Huffman 2007).

A positive relationship has been found between alcohol availability and drinking and binge drinking (Chaloupka and Wechsler, 1996). Other important factors identified empirically are type of drink (with students drinking beer, liquor or no preferred type being more likely to binge than those who drank wine (Wechsler et al 2000) and promotions (with students who were paying less per drink or who received drinks for a set price also being more likely to binge (Wechsler et al, 2000)). This same study found that males were more likely to binge drink than female students (50% vs 41%) (Wechsler et al 2000). It should be noted that these findings date from the year 2000 in the United States. Contemporary UK trends suggest that some of these patterns may be changing, if they have not already changed. Finally, Okoro, et al (2004) found a link between frequent binge drinking and negative health related quality of life. They suggest that increases in alcohol excise taxes are an effective public health measure to reduce binge drinking.

### **Low income**

No specific evidence was identified on effects of price or taxation on those with a low income. A tax increase sufficient to reduce physical and other consequences of drinking may improve the nation's health and (to the extent that persons with a positive score on this factor impose costs on others) increase its economic efficiency. But it will also reduce the economic well-being of drinkers who continue to regularly consume alcohol, since evidence from the meta-analyses of price elasticities suggests that alcohol has considerable price inelasticity. A study that predates the scope of this review found that when income falls so does alcohol consumption (Adrian & Ferguson, 1986).

### **Harmful drinkers**

Laixuthai and Chaloupka (1993) looked specifically at how price would affect heavy drinking. Given a model of addiction one might suppose that heaviest drinkers should be least affected by price. However some studies have found that heavy drinkers may be more affected by increased prices than moderate or occasional drinkers. This could be explained, at least in part, by the idea that when consuming large quantities as a necessity, a small price increase has a larger effect but when drinking occasionally as a luxury or "treat," price is less important. The study found that raising beer prices through taxation would cut both the overall number of young drinkers and the number of those who drink heavily. Other studies have come to similar conclusions. Research suggesting that price affects consumption even amongst addicts runs across the addictions field (including tobacco) (Manning & Finch, 2003). Wagenaar (2008) found in his meta-analysis that price/tax also significantly affects heavy drinking ( $p < .01$ ), but the magnitude of effect is smaller than effects on overall drinking.

Chisholm et al's (2004) modelling work projected that in populations with high prevalence of heavy drinkers (more than 5%) [e.g. Europe and North America] taxation was both the most effective and cost-effective intervention. Beer taxes have a small impact on consumption and heavy drinkers are the least responsive to price (Mast et al, 1999). Coate & Grossman (1988) found that fractions of fairly heavy (3-5 cans) and heavy drinkers (6+ cans) declined more in

both absolute and percentage terms than did fraction of light drinkers (1-2 cans) in response to price increases. Laixuthai & Chaloupka (1993) suggested that increasing beer taxation and/or increasing MLDA reduce youth's frequency of alcohol consumption and their heavy drinking. Increasing taxation on alcohol to keep pace with inflation would lead to a 19% reduction in heavy drinking by youths and 6% reduction in high-risk drinking. Finally, Cook and Tauchen (1982) in a study predating the coverage of this review, found that higher alcohol taxes reduce death rates from cirrhosis (presumably occurring primarily amongst alcoholics) more than they reduce consumption in general.

### 1.5 Summary

An increase in the price of alcohol has been found to reduce alcohol consumption, hazardous and harmful alcohol consumption, alcohol dependence, the harm done by alcohol, and the harm done by alcohol to others than the drinker. Policies that regulate the alcohol market, including the price of alcohol, the location, density, and opening hours of sales outlets and controls on the availability of alcohol have been found to have an impact in reducing drinking and driving and related fatalities (Grube and Stewart 2004). The exact size of this impact varied between countries and a major limitation of the evidence base is that most studies examining the impact of such policies have been conducted in the United States.

Nevertheless, there is very strong evidence for the effectiveness of alcohol taxes in targeting young people, heavy drinkers and the harmful effects of alcohol.

Possible policies:

- Increase alcohol duty and link alcohol taxes to inflation (cf Anderson and Baumberg 2006).
- Link levels of taxation to alcohol strength, including introduction of tax incentives for low-alcohol alternatives
- Minimum pricing
- Policies targeting price-based promotions

This review has examined the evidence base on the influence of price and price changes on alcohol consumption and harm. It has found evidence of a clear relationship that taxation or price increases serve to decrease consumption and associated harms. A potential collateral impact of policies leading to large price rises in terms of stimulation of a covert, illegal trade that needs to be borne in mind.

Rigorous efforts were taken to identify research studies or evaluations examining price-based promotions in the off-trade. While there is little empirical research investigating minimum pricing the putative mechanisms for this as a public health policy are clearly associated with the wider taxation and pricing evidence base. There is scattered evidence that suggests that the various pricing policy options have a similar or stronger effect for the identified at-risk groups (young people under 18, young adult binge drinkers, and, in some studies, heavy drinkers) and may thus be especially suitable for reducing overall harms in these groups.

**Table 2 Studies linking pricing to consumption**

| <b>Authors<br/>Country</b>         | <b>Study Design</b>                     | <b>Sample and<br/>Interventions</b>  | <b>Methods</b>   | <b>Consumption<br/>Outcomes</b>   | <b>Limitations and Conclusions</b>   |
|------------------------------------|---|--|--|---|--|
| Bradizza et al (2006)<br>USA       | Qualitative study using 10 focus groups | <b>Sample</b><br>53 young adult men and women who regularly consume liquor (i.e. 40oz/week). Mean age 24 yrs.  | <b>Outcome Measures</b><br>Attitudes to Malt liquor<br><br><b>Data analysis</b><br>Focus groups explored unique characteristics of malt liquor (low price, high alcohol content, large volume packaging) that enhance consumption patterns and increase risk for excessive alcohol use. Group transcripts analysed for recurring themes                    | Malt liquor was instrumental (quick intoxication) as well as practical (inexpensive) choice.<br><br>Malt liquor viewed as beverage consumed by individuals who were struggling financially (economically disadvantages, students, minorities). Its cheap price made it possible to enjoy drinking alcohol without forgoing life essentials.                                 | <b>Limitations</b><br>Limited sample size.<br><br><b>Reported conclusions (by authors).</b><br>Found consistency between quantitative and qualitative data.  |
| Chaloupka & Wechsler (1996)<br>USA | Model                                   | <b>Study Setting</b><br>Students in 140 US colleges and universities<br><br><b>Sample at Baseline</b><br>Data from the 1993 Harvard College Alcohol Study<br>n = 17,592 students | <b>Sampling Method</b><br>Self-administered questionnaires collecting sociodemographic information.<br><br><b>Outcome Measures</b><br>Effect of alcohol control policies on drinking<br><br><b>Data analysis</b><br>Probit method to establish relationships between beer price, alcohol availability, drunken driving and laws for youths and young adult | Beer is preferred beverage of choice among drinkers. Price of beer has a negative impact on drinking. The relationship is not significant for underage males but significant in underage and older females.<br><br>Higher beer taxes could reduce binge drinking and underage drinking among college women e.g. There would be reduced drinking participation by 15% if tax | <b>Limitations</b><br><ul style="list-style-type: none"> <li>Reliability of questionnaire of self-reported drinking is questionable.</li> <li>Small effect of price on drinking among students may be caused by measurement error to the price variable i.e. inaccurate reflection of retail prices of alcoholic beverages for college student.</li> <li>Detailed data on prices and sources for alcoholic beverages to students are unavailable.</li> <li>Evidence for existence of causal relationship between campus environment and binge drinking is unavailable.</li> </ul> <b>Reported conclusions (by authors).</b> <ul style="list-style-type: none"> <li>Increase in beer prices or raising excise taxes on</li> </ul> |

|  |                          |   |  |  |  |
|--|--------------------------|---|--|--|--|
| <p>Clements, Yang &amp; Zheng (1997)<br/>Australia</p> | <p>Model</p>             | <p><b>Study Setting</b><br/>Data from 7 countries<br/>Australia,<br/>Canada,<br/>Finland<br/>New Zealand,<br/>Norway,<br/>Sweden,<br/>UK (1955-1985)</p>  | <p><b>Outcome Measures</b><br/>Estimation of conditional income elasticities<br/><br/><b>Data analysis</b><br/>Application of additive utility (preference independence) to demand elasticities for alcoholic beverages.</p> | <p>Price elasticities are less than one in absolute value and spirits are most price elastic than wine and then beer.<br/><br/>Beers, wines and spirits are preference-independent which means that the marginal utility of one beverage is unaffected by changes in the consumption of the other two.</p>                                 | <p><b>Limitations</b><br/>None identified<br/><br/><b>Reported conclusions (by authors).</b></p> <ul style="list-style-type: none"> <li>• Beer should be taxed at almost three times the rate for spirits, while wine tax should be approximately 50% higher than that for spirits.</li> <li>• Beer has the lowest income elasticity and the highest tax rate while spirits are the most income elastic and has the lowest tax rate.</li> </ul>  |
| <p>Costanigro et al (2007)<br/>USA</p>                 | <p>Econometric study</p> | <p><b>Study Setting</b><br/>USA Wine Market<br/><br/><b>Study Sample</b><br/>13,157 observations from ten years (1991-2000) of tasting ratings in Wine Spectator magazine (California &amp; Washington red wines)</p> | <p><b>Outcome Measures</b><br/>Tasting quality ratings<br/><br/><b>Data analysis</b><br/>Computed eight different values for price and then established a "breaking point" to distinguish wine between price categories.</p> | <p>Consumers value wine attributes differently across wines depending on price range. Two market segments can be identified: consumption wines and collectible wines.<br/><br/>Regional appellations have a positive effect on price only for inexpensive or mid-low price segment and are non-significant or negative for higher ones</p> | <p><b>Limitations</b><br/>Only examines red wines from two USA regions. Needs to validation against Europe, South African, South American and Australian markets and for other beverages.<br/><br/><b>Comments</b><br/>Wine is identified as an "experience good" i.e. quality cannot be evaluated before consumption.<br/><br/><b>Reported conclusions (by authors).</b></p> <ul style="list-style-type: none"> <li>• Wine shoppers make purchasing decisions with a price range in mind. Within price-range bottles are compared and a purchasing decision made.</li> <li>• For lower price wines this decision takes place at store whereas for higher priced wines decisions are informed by specialist magazines and reputation of wineries.</li> </ul> |
| <p>Gallet (2007)<br/>USA<br/>3025</p>                  | <p>Meta-analysis</p>     | <p><b>Study Sample</b><br/>132 studies reporting alcohol price elasticities (1945-2003)</p>   | <p><b>Outcome Measures</b><br/>Price elasticities<br/><br/><b>Data analysis</b><br/>Number of observations and median elasticity</p>   | <p>Number of observations (median price elasticity)<br/>Beer 325 (-0.36)<br/>Wine 300 (-0.700)<br/>Spirits 294 (-0.679)<br/>Alcohol 263 (-0.497)<br/><br/>Adult 22 (-0.556)<br/>Young Adult 13 (-0.386)</p>  | <p><b>Limitations</b></p> <ul style="list-style-type: none"> <li>• Differences in specification of alcohol demand across literatures with median elasticities being larger for more recent methods.</li> </ul> <p><b>Reported conclusions (by authors).</b></p> <ul style="list-style-type: none"> <li>• Wine and spirits most responsive to price and income.</li> <li>• Unusual finding suggesting younger individuals are</li> </ul>  |

|   |   |   |   |  |
|---|---|---|---|--|
| <p>less responsive to price than older individuals – may be due to differences in consumption bundles across age groups.</p> <ul style="list-style-type: none"> <li>• Wine has largest income elasticity, followed by spirits then beer.</li> <li>• Given differences in price elasticity across beverages and consumer age groups optimal tax will account for such differences. Optimal tax will account for interdependencies in demand across beverages.</li> <li>• As teens are least responsive to price, reduction of teen alcohol consumption should examine alternatives to taxation e.g. education campaigns.</li> </ul>  | <p>Teen 1 (1.167)</p>   |   |   |  |
| <p><b>Limitations</b></p> <ul style="list-style-type: none"> <li>• Longitudinal data may confound intervention effect with regression to the mean. Partly controlled in this study by distinguishing stable drinkers from reducers and increasers.</li> <li>• Study excluded abstinent responders and very light drinkers</li> <li>• Impulsive consumption associated with presumed bargain opportunities may be responsible for early increase.</li> </ul> <p><b>Comments</b><br/>Findings criticised by Bergler (2003). Industry expert for Groupement Suisse des Spiritueux de Marque.</p> <p><b>Reported conclusions (by authors).</b><br/>Spirits consumption showed price-responsiveness in early post-intervention period. Increase in spirits consumption took place at time of generally declining consumption of alcohol. In contrast to most studies price reduction, increased availability.</p> <p><b>Limitations</b></p> <ul style="list-style-type: none"> <li>• Not all econometric test statistics are conclusive. Therefore further refinements are required.</li> <li>• Not all parameters have been accurately measured by estimation method especially terms for cross-</li> </ul> | <p>Spirits consumption increased significantly (by 28.6%) in total sample and specifically in young males and in individuals who were low volume drinkers at baseline. Consumption of alcohol overall, or of wine and beer, did not change significantly. No indication of effects of substitution.</p> | <p><b>Study Sample</b><br/>Follow up 3 months after price change. Attrition rate from baseline to follow up was 20.2%.</p> <p><b>Outcome Measures</b><br/>Alcohol consumption assessed by beverage-specific graduated frequency measure. High volume drinking was defined as 40+ g/day for men and 20+ g/day for women. Binge drinking was defined as 6+ drinks on an occasion for men and 4+ drinks for women</p> <p><b>Data analysis</b><br/>Used combinations of drinking categories at baseline and follow-up to account for changes due to regression to the mean.</p> | <p><b>Study Setting</b><br/>Reduction in price of spirits in July 1999.</p> <p><b>Sample at Baseline</b><br/>Probabilistic telephone sample of 1347 individuals with at least monthly consumption in previous 6 months. Response rate at baseline was 74.8%</p> | <p>Heeb et al (2003)<br/>Switzerland</p> |
| <p>Estimated elasticities with respect to prices:<br/>On-trade Beer = -0.48<br/>Off-trade Beer = -1.03<br/>Spirits = -1.31</p>  |   | <p><b>Outcome Measures</b><br/>Estimation of the alcohol demand models</p> <p><b>Data analysis</b></p>  | <p><b>Study Setting</b><br/>HM Customs and Excise (HMCE) (1970-2002)</p>  | <p>Huang (2003)<br/>UK</p>               |

|  |                              |  |   |  |  |
|--|------------------------------|--|---|--|--|
|  |                              |  | <p>A co-integration modelling approach.</p> <p>4 sets of empirical demand models built for on-trade beer, off-trade beer, spirits, and wine excluding coolers.</p> <p>Model follows a single-equation approach based on the standard consumer demand theory.</p>  | <p>Wine = -0.75</p> <p>Estimated elasticities with respect to income:<br/>                 On-trade Beer = -0.18<br/>                 Off-trade Beer = 0.55<br/>                 Spirits = 0.69<br/>                 Wine = 1.51</p>   | <p>price elasticity.</p> <p><b>Reported conclusions (by authors).</b><br/>                 Plausible own-price and cross-price elasticities have been estimated for the UK up to the year 2002. As income goes up, people buy more off-trade beer, spirits and wine, but not on-trade beer – the authors suggest that on-trade beer may be considered an inferior good.</p>  |
| <p>Keng &amp; Huffman (2007)<br/>                 USA<br/> <b>Binge drinkers</b></p> | <p>Econometric modelling</p> | <p><b>Study Setting</b><br/>                 National Longitudinal Survey of Youth (1979-1994)</p> <p><b>Sample at Baseline</b><br/>                 American adults, blacks, Hispanics and economically disadvantaged youth</p> <p><b>Study Sample</b><br/>                 12,686 young men and women (14-21 yrs)</p> <p>Data for the price and alcohol: <i>Cost of Living Index (1978-1995)</i></p> | <p><b>Outcome Measures</b><br/>                 To investigate effect of Increasing alcohol prices on probability of individuals engaging in heavy binge drinking</p> <p><b>Data analysis</b><br/>                 Two fitted econometric models presented</p> <p>Long-run and short-run elasticities of binge drinking</p>   | <p>Binge drinking is price responsive to the price of alcohol: 1% increase in local alcohol price decreases the probability of an individuals engaging in heavy binge drinking by 2.36 and 1.29% in long run and short run, respectively.</p> <p>Binge drinking by young people is highly responsive to state taxes on alcohol.</p> <p>Increase in local alcohol price decreases occasions of binge drinking, and thus the individual is less likely to become a binge drinker.</p> <p>1% increase in alcohol price has short-run effect on raising annual earnings by 0.21% and a long-run impact of 0.45%.</p> | <p><b>Limitations</b></p> <ul style="list-style-type: none"> <li>Empirical results support rational addiction model that individuals drinking behaviour is rational and that binge drinking, health status and earnings are jointly determined.</li> <li>Data used are limited to individuals younger than 40. Therefore negative effect of binge drinking on health and earnings may be even greater for older individuals.</li> </ul> <p><b>Reported conclusions (by authors).</b></p> <ul style="list-style-type: none"> <li>Individual's demand for binge drinking can be reduced significantly by increase in alcohol price.</li> <li>As NLSY79 cohort becomes older, there will be more research into effects of binge drinking and other decisions e.g. health investment and earnings</li> </ul> |
| <p>Kuo (2003)<br/>                 Switzerland</p>                                   | <p>Longitudinal study</p>    | <p><b>Study Setting</b><br/>                 Tax reform led to 30-50% decrease in price for foreign spirits.</p> <p><b>Sample at Baseline</b><br/>                 4007 residents aged 15 years or older participated in baseline survey 3 months before tax reform.</p>   | <p><b>Study Sample</b><br/>                 73% participated in follow up survey 28 months after reform.</p> <p><b>Outcome Measures</b><br/>                 Alcohol consumption; drinking habits, problem drinking and purchase of spirits.</p> <p><b>Data analysis</b><br/>                 Increase in spirits consumption persisted even after adjustment for significant</p> | <p>Consumption of spirits increased after price of spirits decreased. Increase in spirits consumption consistent across subgroups, except group aged 60 or older.</p> <p>Younger people are more affected by price than older persons.</p>   | <p><b>Limitations</b></p> <ul style="list-style-type: none"> <li>Used self-report</li> <li>Longitudinal study subject to attrition</li> </ul> <p><b>Reported conclusions (by authors).</b><br/>                 Younger people are more affected by price than older persons. Price should be considered an effective policy to reduce alcohol misuse and alcohol-related problems, especially among the younger population.</p>   |

|  |                                 |  |   |   |   |
|--|---------------------------------|--|---|---|---|
| <p>Goudie et al (2007)<br/>UK</p>      | <p>Hypothetical experiments</p> | <p><b>Study Sample</b><br/>40 current polysubstance misusers (29 males, 11 females; mean age 23.8)</p>                                   | <p><b>Study Method</b><br/>Participants asked to hypothetically purchase drugs from price list of alcohol, amphetamine, cannabis, cocaine and ecstasy at different levels of quality and price (i.e. better quality drugs cost more money). Disposable income available was systematically varied to determine impact of income on decision to purchase drugs.</p>  | <p>Demand for both normal alcohol and strong alcohol was income inelastic.</p>  | <p><b>Reported conclusions (by authors).</b><br/>Higher prices for alcohol reduce important dimensions of current alcohol dependence and abuse.</p> <p><b>Limitations</b><br/>Hypothetical drug purchasing decisions and self reported drug preference</p> <p><b>Reported conclusions (by authors).</b><br/>Like other products, controlled drugs are purchased based on consumer's interpretation of their relative value. It is probable that purchase and subsequent use of controlled drugs by polysubstance misusers will be heavily influenced by economic environment.</p>   |
| <p>Gruenewald et al (2006)<br/>USA</p> | <p>Econometric modelling</p>    | <p><b>Study Setting</b><br/>Sweden</p> <p><b>Study Sample</b><br/>Swedish price and sales data provided by Systembolaget (1984-1994)</p> | <p><b>Outcome Measures</b><br/>Own price effects and cross price effects</p> <p><b>Data analysis</b><br/>Sales were detrended and deseasonalised prior to analysis. Seemingly unrelated regression equations used to model impacts of price increases within 9 empirically defined quality classes across beverage types. Models enabled statistical assessments of both own-price and cross-price effects between types and classes.</p> | <p>Consumer behaviour is responsive to changes in prices.</p> <p>Rather than reducing consumption drinkers switch to lower cost brands to maintain their consumption.</p> <p>Quality/quantity trade-offs exist within a beverage type and across beverage types. Results showed that consumers respond to price increases by altering their total consumption and by varying their brand choices. Significant reductions in sales were observed in response to price increases, but effects mitigated by significant substitutions between quality classes. Findings suggest net impacts of purposeful price policy to reduce consumption will depend on how such policies affect range of prices across beverage</p> | <p><b>Limitations</b></p> <ul style="list-style-type: none"> <li>• Sales used as proxy for consumption.</li> <li>• Price series were unweighted averages of brands within each quality class meaning that brand with low sales was as influential as high-selling brand.</li> <li>• Excludes low alcohol brands which were not sold through outlets</li> <li>• Excludes illegal production.</li> <li>• Does not analyse differential effect of quality.</li> <li>• Does not use symmetry of cross-price effects.</li> <li>• Only looks at demand side of market.</li> </ul> <p><b>Reported conclusions (by authors).</b><br/>Concentrating on inexpensive forms of alcohol is more likely to restrict sales by preventing substitution.<br/>Manufacturers maintaining several brands may adjust pre-tax prices to maintain prices for low-end beverages but raise them for high-quality brands. Price-posting may be a way of countering this. If younger or heavier drinkers focus disproportionately on low cost beverages increasing</p> |

|  |  |  |  |              |                                    |
|--|--|--|--|--------------|------------------------------------|
| <p>these prices may be particularly useful.<br/>Alcohol is composed of different beverage types (i.e., beer, wine, and spirits) and quality brands (e.g., high-, medium-, and low-quality beers). Consumers may make substitutions between different beverage types and brands in response to price increases. Availability of a broad range of beverage prices provides opportunities for consumers to mitigate effects of average price increases through quality substitutions; a change in beverage choice in response to price increases to maintain consumption.<br/>Assessed relationships between alcohol beverage prices, beverage quality, and alcohol sales and examined price effects on alcohol consumption</p>   |  |  |  |              | <p>Hollingworth (2005)<br/>USA</p> |

## Review 2: The effect of promotion on alcohol consumption

### 2.1 Introduction

Alcohol occupies a prominent place among branded consumer goods. Alcohol products are particularly attractive to young people who see them as a way of signalling their adult identity and their entrée into adult society. Producers and marketers of alcohol are using increasingly sophisticated promotional mechanisms. Unintended effects of otherwise legitimate marketing strategies may include underage drinkers starting to drink, regular young drinkers becoming prone to binge drinking patterns and established young drinkers accruing a heavy level of consumption which can place them at risk of harms (Academy of Medical Sciences 2004).

Sophisticated and innovative promotional marketing mechanisms usually operate in advance of rigorous academic research and evaluation. As a consequence, there is a large evidence base, although comprised mainly of study designs that are unable to demonstrate a causal effect, around established channels such as the mass media but a shortage of studies evaluating newer media such as the internet and mobile phones. Generally, the vast array of channels and of types of promotional activity (Jernigan and O'Hara 2004) make it difficult to isolate individual effects, and thus target individual strategies, even though they consistently demonstrate an aggregative effect. Policy options should therefore recognise where a common underpinning mechanism exists and apply general principles to target such a mechanism in anticipation of new channels rather than continually attempt to respond to specific evidence on every new medium. This takes account of the fact that promotion is never static, even in established markets, as new cohorts of young people, with new media preferences, become targets for marketing activity as they mature (Saffer 2002).

#### 2.1.1 Structure of this review

This review begins by considering an important meta-analysis that examines the impact of advertising on consumption in general (Section 2.2). It then proceeds to examine the more micro effect of advertising and promotion on consumption (Section 2.3) focusing firstly on the substantial quantity of research that exists around mass media evidence (e.g. TV, press), before looking at work on the use of promotional items (e.g. T-Shirts). Section 2.4 examines measures put in place to restrict advertising (either total bans or partial restrictions). Finally Section 2.5 considers measures that might be put in place to attempt to respond to the effect of advertising such as counteradvertising and public service announcements (to follow).

#### 2.1.2 Summary of quantities of evidence by topic

This review attempts to include both significant primary studies and the results of systematic reviews. The following table reports the respective yield for the major sections of this report.

**Table 6 Number of studies included and covered (Review 2)**

| <i>Section</i>   | <i>Number of studies included</i>      | <i>Number of studies covered<sup>a</sup></i> |
|--|--|--|
| Advertising in general (Section 2.2)                               | 2 systematic reviews and meta-analyses | 132 econometric studies and 7 cohort studies |
| Specific advertisements and promotions (Section 2.3)               | 57 and 1 meta-analysis                 | 65   |
| Bans and other restrictions (Section 2.4)                          | 10                                     | 10   |
| Counter Advertising and Public Service Announcements (Section 2.5) | To follow in final report              | To follow in final report                    |
| Total  | 70                                     | 207  |

<sup>a</sup>This includes studies accessed via the results of large meta-analyses or studies that, due to logistic constraints or agreed limitations of the scope of this review (e.g. date, language etcetera), are not included in the accompanying evidence tables.

## 2.2 Measuring the impact of alcohol advertising

Gallet's (2007) meta-analysis of 132 studies reporting elasticities has already been analysed in the section on price and consumption. As previously mentioned his meta-analysis is of reasonable quality and certainly superior to any such analysis possible within the time and resource constraints of these reviews. In addition to data concerning price elasticities, Gallet reports data on advertising elasticities (322 values). Again special emphasis is given to studies conducted in a UK setting or to those completed subsequent to his data collection.

A further systematic review specifically looking at the link between alcohol advertising and consumption in young people was conducted by Smith and Foxcroft (2007).

### Details of studies

132 studies are included in Gallet's (2007) meta-analysis. All studies were published in English, with the earliest being published in 1945 and the most recent in 2003. The majority of studies were conducted in the USA. An initial search of Econlit was supported by follow up of references from traditional narrative reviews and from included studies, and supplemented by internet searches. Advertising elasticities were used as the units of analysis.

In their systematic review of the effect of advertising on youth alcohol consumption Smith & Foxcroft (2007) found 7 cohort studies from a variety of settings including USA, Belgium and New Zealand.

### Outcomes

In the Gallet (2007) meta-analysis studies measured advertising elasticity using a variety of methods for specifying alcohol demand. In the Smith and Foxcroft (2007) review outcome measures for alcohol consumption included any alcohol use in the past month, any alcohol use in the past year, drinking frequency, drinking frequency at specific locations and alcohol use whilst going out.

### Results

Gallet (2007) reports median advertising elasticities for beer (0.020); wine (0.007); spirits (0.070) and alcohol (0.032). An advertising elasticity for Beer of (0.020) means that for every 10% increase in advertising expenditure, the expenditure on beer increases by 0.2%.

Findings from the systematic review by Smith and Foxcroft (2007) demonstrate a consistent picture of the association of advertising with initiation, consumption and heavy drinking.

Specific findings included the following:

- Males who reported being aware of more alcohol advertisements at age 15 drank significantly more beer at 18 years. In beer drinkers aged 18, liking of alcohol advertising had a positive impact on beer consumed at age 21 years and they were more likely to be heavy drinkers at 26 years (New Zealand).
- In school children increased viewing of TV programmes with alcohol advertisements increased chance of beer consumption one year later (United States).
- Exposure to in-store beer displays significantly increased the chance of alcohol consumption two years later in adolescents (United States)..
- In 15 to 26 years olds in the USA, for each additional advertisement seen the number of alcohol drinks consumed increased by 1% (United States).
- In school children for each additional hour of TV viewing per day there was a 9% increased risk of initiating drinking 18 months later (United States).
- Increased hours of TV and music video viewing were associated with higher quantity of alcohol consumed one year later in school children (Belgium).
- School children were significantly more likely to have tried alcohol for the first time at follow-up at one to two years following greater exposure to alcohol portrayals in popular movies (United States).

It is interesting to note that these effects may be demonstrated for both under age and young adult drinkers and that they persist over a wide range of advertising channels that include both direct and indirect exposure.

### **Limitations**

Studies included in the Gallet (2007) meta-analysis estimated advertising elasticities using high-level aggregates of advertising expenditure, mostly with short-run series. It needs to be borne in mind that this approach to estimating the effect of advertising does not differentiate between different form of advertising or groups of drinkers, and has been criticised on methodological grounds. Saffer (1996) argued that “. . . studies that use national data on annual alcohol advertising expenditures measure advertising at a high level [of aggregation] with little yearly change and are likely to find no effect on consumption” (Saffer, 1996, 266).

Cohort studies, as identified by Smith and Foxcroft (2007), can be prone to confounding and although some confounding variables were identified, the authors conclude that it is not possible to know if residual confounding influenced the analysis. Furthermore, they state that given the magnitude of the effect sizes shown in these studies, it is possible they were due to residual and unmeasured confounding.

A final limitation is that there is significant debate on whether advertising effects can be adequately estimated using the methodologies and data underlying the above studies. The main criticisms are: 1) oversimplification of consumer decision making process and disregard of the mechanisms through which advertising influences consumers, 2) the mismatch between marketing science and actual business: If the elasticity of advertising expenditure, as in Gallet, really lies between 0 and .07, why would any business spend such significant amounts on advertising? and 3) in a market where there is advertising saturation, it may be difficult to detect effects of marginally higher or lower advertising expenditures.

**Evidence statement 5: There is conclusive evidence of a small but consistent association of advertising with consumption at a population level. There is also evidence of small but consistent effects of advertising on consumption of alcohol by young people at an individual level.**

**Evidence statement 6: There is an ongoing methodological debate on how advertising effects can and should be investigated and further research and methodological developments for establishing a definite causal relationship is required.**

Gallet's meta-analysis is supplemented by consumer studies, which show that alcohol advertisements tend to lead to positive expectancies and attitudes about alcohol. Such consumer studies also provide increasing evidence that exposure to alcohol advertisements increases initiation of alcohol use amongst adolescents. These can be ranged alongside evidence from econometric studies with the majority finding a positive association between the volume of advertising and drinking behaviour and outcomes.

## **2.3 Specific types of advertising and promotion**

### **2.3.1 Price & Point of Sales Promotions**

A large proportion of on- and especially off-trade alcohol is sold “on deal”, with expert estimates quoting that as much as 40-50% of all alcohol sold in supermarkets is sold whilst on promotion (personal communication May 2008). A considerable number of retailers offer promotional deals and ‘happy hours’ (temporary price-cuts) on products regularly consumed by young drinkers (see Hastings et al. 2005). Examples include: a never ending vodka glass (purchase one glass of vodka and refill it as often as you like); free first drink for girls, buy-one-drink and get one-free promotions, and cheap deals on popular drinks on particular nights of the week. Alcohol price promotions are associated with increased binge drinking (Kuo et al. 2003). Fisher (2005) models what he terms “happy hour economics” whereby monopolistic competition causes seasonal increases in demand which in turn lead to decreases in price.

All of the below studies consider the effects of price and promotions at the point of sale. A narrative synthesis is preferred here because of the heterogeneity of studies in this sample. No systematic reviews were found. This review therefore comprises 12 individual studies covering promotion-related interventions.

### **Details of studies**

12 studies met the inclusion criteria. All studies were published in English, with the earliest being published in 2000. The large majority of studies were conducted in the USA, with isolated examples from the UK, New Zealand and Australia. Longitudinal studies were the most common design with other designs including surveys and audits. The studies varied in populations with their being several with considerable ethnic variation from a UK population. Some studies considered particular at risk groups such as under age drinkers, heavy drinkers and binge drinkers.

### **Outcomes**

The most sophisticated measurement of outcomes was used in the study by Kuo et al (2003) which used an *off-premises establishment index score* which included a summed score of 5 items; sale of party balls or kegs, low sales price on 12 and 24-packs, any beer promotions and exterior and interior ads. They also computed an *on-premises establishment index score*, which included a summed score of 8 items: beer specials, special promotions in the following 30 days, low sale prices, interior and exterior signage, promotions, no interior or exterior signage of alcohol warning and any age verification policies. The two establishment indices were then combined to produce a single *total alcohol environment score*, with high scores indicating an “drink-friendly” environment. .

### **Results**

Probably the most relevant study to this particular issue is that by Kuo et al (2003). This study does show the greatest sensitivity with regard to different elements of point of purchase promotion. This study found that campuses with higher off-premise establishment index scores had statistically significant higher binge-drinking rates. Similarly the on-premise establishment index score indicated that campuses with higher on-premise scores also had higher binge-drinking rates. Furthermore a significant correlation was found for the total environment score and college binge-drinking rates ( $r=0.49$ ), past 30-day drinking rates ( $r=0.41$ ), and past year drinking rates ( $r=0.35$ ). In summary then the higher the alcohol environment score, the higher the percentage of binge drinkers, past-30-day drinkers or past-year drinkers on campus. The study by Pedersen (2002) also indicates that binge drinkers are likely to be differentially impacted by promotions albeit in a campus newspaper. A study by Babor et al (1978) which predates coverage of this review describes a drinking experiment recording quantity consumed during happy hour prices and when prices were regular. This study found that consumption increased significantly during the happy hour but returned to prior levels after the promotional period ended. The effect was found for both occasional and heavy drinkers.

### **Limitations**

As shown in the introduction, a very wide range of promotional activity is used in alcohol marketing and many of these have not been researched. Any conclusions drawn from individual studies are necessarily dependent on the degree to which it is believed that a common mechanism or mechanisms exists between similar-looking promotions. This has important implications as to those promotions that are to be specifically targeted and as to how such promotions are defined, classified and grouped.

College students are most commonly studied and issues can be identified with respect to both the lack of representativeness and motivation to participate. As with many advertising and promotion studies, it is common to find participants being recruited through a marketing course. Thus, the study by Kuo et al (2003) focused on college students, although Hertz et al (2007) have extended findings to cover school children. An important confounding variable is the omnipresence of extensive media advertising, which makes it particularly difficult to isolate in-store promotional effects.

### **Summary**

The fact that the studies are so heterogeneous makes direct comparison difficult. There is evidence to suggest that promotional activity at the point of purchase has a significant impact on the likelihood for young people to consume alcohol and also to binge drink. However, causality cannot be inferred from the included study designs. It is important to note that point

of purchase promotions are likely to extend their influence to the young drinking population and to under-age drinkers.

**Evidence statement 7: There is moderate but consistent evidence to suggest that point of purchase promotions are likely to affect the overall consumption of under age drinkers, binge drinkers and regular drinkers.**

### **2.3.2 Billboard & Print Media**

Typically advertisements in the form of billboards and magazines promote beer or spirits rather than wine (Garfield et al, 2003). However there is also a distinct target audience for advertisements for wine among young adults. Frequently billboards present party scenes (Mastro & Atkin, 2002) promoting the social desirability of alcohol-supported recreation. Increasingly in recent years these advertisements feature ready-to-drink products. Alcohol companies place significant amounts of advertising where youth are more likely per capita to be exposed to it than adults (Jernigan et al. 2005). A study of young people in Ireland (Dring & Hope 2001) found billboards were the second most common vehicle for alcohol advertisements after TV. Fleming et al (2004) found that awareness of advertising via billboards amongst an under age population was as high as 60%.

This section considers use of billboards and print media such as newspapers and magazines. In the UK poster and magazine advertising of alcohol-related products are regulated by the Advertising Standards Authority (ASA). A narrative synthesis is preferred here because each of these methods of advertising is fundamentally different and contributes to its own specific evidence base. No systematic reviews were found. This review therefore comprises individual studies that cover such media as billboards, magazines and newspapers

#### **Details of studies**

10 studies met the inclusion criteria. Most of these examined either magazines or billboards. All studies were published in English, with the earliest being published in 1997. Most studies were conducted in the USA. Several studies examined specific at risk groups of interest specifically underage drinkers and binge drinkers.

#### **Outcomes**

Studies typically measured exposure to advertising materials and its association with awareness, drinking intention or drinking behaviour. Most studies were cross-sectional although occasional studies used a longitudinal design.

#### **Results**

Several studies report a link between the appeal of printed advertisements and subsequent likelihood of consumption. Some studies simply audit exposure to advertising in magazines. Dring & Hope (2001) measured awareness of billboard advertising through self completed questionnaire and found that for young people 'selling aspects of alcohol advertisements relate to linking alcohol to positive images of desirable lifestyles and little to do with selling the actual alcohol product advertised. There is some evidence that exposure to advertising extends beyond their explicitly intended audience to younger, under age children. The primary effect for these appears to be on the initiation of drinking. Once drinking has been initiated, exposure to advertisements raises brand awareness and several studies also indicate an effect on the volume and frequency of drinking.

Ellickson et al (2005) conducted a longitudinal study which examined exposure to magazines with alcohol advertisements amongst 7<sup>th</sup> grade drinkers and found this was predictive of frequency of drinking two years later.

Of particular concern has been the proximity of billboards to schools. Mastro & Atkin (2002) examined this issue through a content analysis. They found, however, that the images presented were not particularly salient to their study population of Mexican American High school students. This issue needs to be investigated in a UK context. There is some evidence from the same study that students are not able to distinguish between images promoted through billboards from magazines and other advertising media suggesting that a cumulative

effect arises from the multiple channels of advertising. Clearly this is important as restrictions on one form of advertising have frequently been reported to result in a transference of effort and advertising expenditure to other channels. Restricting advertising on billboards only, for example, is unlikely to have a significant effect on consumption especially given the relatively small overall effects of advertising in general (see above).

### **Limitations**

Many of these studies use opportunistic USA student populations and are not generalisable to the typical population of UK young people. In addition many are cross-sectional and rely on self-report data making it difficult to establish whether anticipated behaviour as expressed through intention actually translates to actual behaviour. It is doubtful whether large surveys conducted by the Center of Alcohol Marketing in Youth (U.S) on Hispanic and African American youths have relevance to a UK population.

### **Summary**

Studies are primarily surveys and cross-sectional studies so cannot be used to establish causality. Nevertheless there is a consistent picture from findings for various print-based media of an association between increased awareness and increased consumption. Through high exposure to recurring positive messages about alcohol over time young people have their attitudes or beliefs shaped or reinforced. This, in turn, can influence their intention and subsequent drinking pattern. It is important to consider this evidence as part of a general "marketing mix". Snyder et al (2006), for example, examined the effects of billboards within the context of an index of exposure covering four media (TV, radio, billboards and magazines) and). However, such an approach means it is not possible to disentangle the effects of individual communication channels and must be complemented by media-specific investigations.

**Evidence statement 8: There is consistent evidence to suggest that exposure to outdoor advertising, or advertisements in magazines and newspapers may increase the likelihood of young people starting to drink, the amount they drink, and the amount they drink on any one occasion. Further research is required on whether what young people say they are going to do at a particular point in time translates into actual subsequent behaviour.**

### **2.3.3 Alcohol related merchandising**

Four USA-based studies were identified that examined the use of alcohol related merchandising. All of these studies consider the impact of alcohol related merchandising in relation to alcohol awareness or participation. Fisher et al (2007) found that possession of or willingness to use alcohol promotional items was associated with an increased likelihood of alcohol initiation, significantly so for girls. Furthermore they observed that among girls, possession of or willingness to use alcohol promotional items was associated with binge drinking. Among those precontemplating drinking these items had a greater effect than advertising. Similarly Hertz et al (2007) found that one in five students in surveyed California middle schools owned at least one alcohol promotional item. Ownership of such items was again associated with being 3 times more likely to have tried drinking and 1.5 times more likely to report current drinking than students without such items. Two studies by Workman (2003 and 2004) examined the effects of such items in underage and binge drinking subsamples. While resisting causal inferences the studies did find high prevalence of ownership of promotional items relating to alcohol and located such items within an "already saturated" culture of pro-drinking.

**Evidence statement 9: There is consistent evidence from cross-sectional studies that there are high levels of ownership of alcohol related merchandise among young people, particularly underage drinkers and binge drinkers. There is some evidence, although not conclusive, to suggest that ownership of such items is associated with initiation or current drinking.**

### 2.3.4 Broadcast media

This category includes TV, films, radio, music and music video as well as the Internet. A narrative synthesis is preferred here because of the heterogeneity of these methods. No systematic reviews of use of broadcast media were identified.

TV is by far the most studied channel for alcohol advertising with studies analysing content or frequency of commercials, awareness by young people and association with drinking initiation of levels or frequency of drinking. The principal longitudinal studies have been identified from the review by Smith & Foxhurst, 2007 and are discussed below..

#### Details of studies

31 studies met the inclusion criteria. All studies were published in English, with the earliest being published in 1988. 21 studies were conducted in the USA, 5 in the UK, 3 in New Zealand and 1 in Belgium and 1 in Canada. Ten studies employed longitudinal designs with one being a prospective cohort study. Two econometric studies examined total advertising spend. There was one qualitative study. The majority of studies targeted under age drinkers. Two studies specifically targeted binge drinkers as the population of interest.

#### Outcomes

As with the preceding print media category studies typically measured exposure to advertising materials and its association with awareness, drinking intention or drinking behaviour. Most studies were cross-sectional although occasional studies used a longitudinal design.

#### Results

In the longitudinal study by Robinson et al. (1998) the research team investigated the association between hours of TV, music video and videotape viewing, computer and video game use and subsequent alcohol use at follow-up. The population was 14 to 15 year olds from six public high schools in California. At 18 month follow-up, 36.2% baseline non-drinkers began drinking and 50.7% drinkers continued to drink. In baseline non-drinkers onset of drinking was significantly associated with hours of TV viewing at baseline. Each additional hour of TV viewing per day increased the risk of starting to drink during the next 18 months by 9% (95% CI: 1% to 18%). For each additional hour of music video viewing average increased risk was 31% (95% CI: 17% to 47%). Computer and video game use was not associated with initiation of drinking. In baseline drinkers there were no significant associations between baseline media use and *maintenance* of drinking

In a further longitudinal study Van Den Bulck (2005) examined the relationship between TV viewing and music video exposure and subsequent alcohol consumption one year later in first and fourth year secondary school students in Belgium. 63.6% watched music videos at least several times a week, about a third watched daily. Overall TV viewing and music video viewing at baseline significantly predicted the amount of alcoholic beverages adolescents consumed one year later while going out.

#### Limitations

As with the category billboard and other print media studies are primarily cross-sectional and are therefore limited with respect to establishing causality. Two longitudinal studies, by Robinson et al (1998) and Van Den Buick (2005) were identified. However longitudinal studies do have acknowledged limitations in connection with the existence of possible confounders. In this case, for example, it is difficult to isolate the effects of broadcast media from other significant communication channels such as billboards, newspapers and magazines and from the effects of ownership of alcohol-related merchandise. Several studies are limited in examining the effects of home-viewing of videos rather than new technologies such as DVDs.

**Evidence statement 10: There is consistent evidence from longitudinal studies that exposure to TV and other broadcast media is associated with inception of and levels of drinking. Evidence for the effect of watching videos is equivocal.**

## **2.4 Advertising bans and other restrictions**

There is increasing interest in the impact of a complete ban on alcohol advertising (TV, radio and billboards). All of the included studies consider the impact of advertising bans/restrictions in various forms. These could be bans relating to particular media, to particular populations or total bans on alcohol-associated advertising. A narrative synthesis is preferred here because of the heterogeneity of studies in this sample. This review comprises ten individual studies that cover advertising bans ranging from partial to total bans.

### **Details of studies**

10 studies met the inclusion criteria. All studies were published in English, with the earliest being published in 1991. With one exception, all studies were conducted in the USA. Nevertheless, some of these studies constitute international comparative studies using cross-national level data. Studies represent either econometric studies projecting the effect of a ban or natural experiments where the effect in a particular country or region has been evaluated. No studies specifically examined the differential effect of bans on different types of drinkers. However, the study by Saffer & Dave (2003) did identify a price-binge participation elasticity.

### **Policy measures**

Studies describe a range of levels of ban ranging from partial to complete. The analysis by Saffer and Dave (2002) analyses the correlation between per capita consumption in litres with the number of advertising bans enacted in each country. This has been criticised as a crude measure of ban enactment.

### **Outcomes**

Most of the studies measure total consumption of alcohol. One study measures intention to consume.

### **Results**

As previously noted the meta-analysis by Gallet (2007) suggests that, since the median advertising elasticity estimate is quite small, there is support for studies that have found that advertising bans have little impact on demand. It is likely that advertising bans in themselves will likely have only modest effects and will need to be augmented by additional methods such as taxation and price increases. This finding is supported in a UK context by a study by Godfrey (1994) that suggested that a 1 percent decrease in alcohol advertising would be associated with a 0.1 percent decrease in consumption. Nevertheless, with considerable amounts of alcohol-related advertising expenditure currently taking place in the UK large decreases could potentially have a disproportionate impact on hazardous drinking and related harms.

The study by Saffer & Dave (2003) identified an elasticity of advertising with respect to binge participation of about 0.14, showing that alcohol advertising has a positive effect on binge participation. Based on this data they estimate that complete elimination of alcohol advertising could reduce adolescent monthly alcohol participation by about 24 percent and binge participation by about 42 percent. For binge participation, the effect of complete elimination of advertising would be equivalent to about an 80 percent increase in price. An earlier study by Saffer (1991) found that countries with complete bans on TV alcohol advertisements had 11% lower consumption rates and 23% lower motor vehicle fatalities rates than did countries with partial restrictions.

Proponents of the case that bans of advertising will not reduce consumption consistently argue that advertising merely competes for market share. In harmony with this hypothesis, Fisher & Cook (1995) found, by analysing U.S data from 1970 through 1990, that although years with higher total wine and spirits advertising had higher relative levels of consumption, a model accounting for changes over time found no evidence that changes in advertising were related to changes in consumption. Results did however indicate that increased advertising of spirits was linked to a drop in the market share for wine, suggesting that such advertising may realign market share.

### **Limitations**

It should be noted that the effectiveness of a particular intervention involving a form of ban will

be determined by a number of other factors. These include the existing effectiveness of a particular channel of communication which may vary across cultures, settings and populations, the degree of enforcement and the facility for advertisers to redirect their resources to other channels that might thus escape the effect of a ban e.g. product placement or event sponsorship. In support of this, Seldon et al (2000) found that beer producers would be able to substitute fairly easily with print advertising should a TV or radio ban be enforced again suggesting that a partial ban is unlikely to succeed.

Similarities with findings for taxation are also relevant in that an advertising ban (as with high rates of alcohol taxation) may be reflective of a general climate of alcohol intolerance. It is difficult to extract the specific effect of an advertising ban from these other variables. Chisholm et al (2004) model the effects of such a ban in terms of a between 2% and 4% reduction in the incidence of hazardous alcohol use. They conclude, as previously mentioned in Review 1, that in a “wet” population with a higher prevalence of heavy drinkers (i.e. more than 5% as is the case in Britain) the most effective and cost-effective intervention was taxation, whereas in “dry” populations with a lower prevalence advertising bans are more effective than taxation.

### **Summary**

Studies examining the effects of alcohol advertising on consumption do not support or counter a hypothesis for a causal relationship. This is mainly attributable to the considerable variation in the use of advertising bans across countries and methodological challenges. It should also be recognised that imposition of a ban may require an extended period of time, within which to affect consumption and even longer to have an effect on harms.

**Evidence statement 11: There is some inconclusive evidence that suggests that advertising bans have a positive effect in reducing consumption. Differences in contextual factors are a likely explanation for these differences. It is methodologically challenging to control for all possible confounding factors.**

**Evidence statement 12: There is some evidence to suggest that bans have an additive effect when accompanied by other measures within a general environment of restrictive measures.**

### **2.4.1 Industry self-regulation of alcohol advertising standards**

This review was unable to find any studies that evaluate the effect of industry self-regulation as a policy measure to restrict advertising content. Given the topic area this finding is not in itself surprising. A review by Anderson, published as recently as 2007, concluded within the specific context of alcohol advertising that: “There is no scientific evidence available that tests the effectiveness of non-statutory regulation or shows that it works in regulating the content of commercial communications or in reducing the volume of commercial communications”.

Regulation of advertising content has three components: legislation (defining appropriate rules); enforcement (initiating actions against violators); and adjudication (deciding whether a violation has taken place and imposing an appropriate sanction) (Swire 1997). In the United Kingdom, the variant currently applied is ‘co-regulation’ where rules are developed, administered and enforced by a combination of government agencies and industry bodies (Caswell and Maxwell 2005). Thus broadcast advertising is co-regulated by Ofcom, the statutory body overseeing content and structure of the communications sector with responsibility for auditing, and the Advertising Standards Authority, acting as a “one-stop shop” for advertising standards and consumer complaints.

Self-regulatory codes of conduct have been developed in some economically developed countries whereby the acceptable and unacceptable content of advertisements is defined and self-monitoring, or some kind of combined industry and government monitoring, is used to examine complaints. Some difficulties highlighted in Australian studies where such a system operates include ample evidence of multiple violations as rated by ordinary members of the public (Saunders 1993) and by experts in marketing (Jones and Sullivan, 2002) - even in

advertisements where complaints were overruled. A formal review of self-regulatory process found significant weaknesses and noted that consequences for breaches were insignificant and often were only applied after a series of adverts had been running for several weeks (National Committee for the Review of Alcohol Advertising, 2003). This Section is not a major focus for this review as the investigators and commissioners are aware of a forthcoming report by government-commissioned report (by KPMG) which handles these issues in more detail.

Several advantages are claimed for self regulation in preference to government regulation. These include increased flexibility and efficiency and, more significantly, that it reduces costs by shifting the cost of developing and enforcing rules to industry and provides greater incentives for compliance (Swire, 1997).

## **2.5 Counter advertising and public service announcements**

Most of these studies consider counter advertising which involves “disseminating information about a product, its effects, or the industry that promotes it, in order to decrease its appeal and use”. The distinction from other types of informational campaigns lies in that it directly addresses the fact that the particular commodity is promoted through advertising (Stewart 1997). Other studies examine public service announcements (PSAs) which are “messages prepared by nongovernmental organizations, health agencies or by media organizations for the purposes of providing important information for the benefit of a particular audience” (Anderson, 2007). PSAs depend upon donated time or space for distribution to the public, typically involving messages that deal with “responsible drinking,” the hazards of driving under the influence of alcohol, and related topics. Despite their good intentions, PSAs are considered an ineffective antidote to the high-quality pro-drinking messages that appear much more frequently as paid advertisements in the mass media. In many cases the messages in PSAs are tailored to be particularly relevant to drinking by youth (Connolly et al. 1994; Holder 1994). In a traditional review, Gorman (1995) identified the limited impact of PSAs, and mass media interventions that use a universal strategy on alcohol use and alcohol-related problems. However in a Canadian study that falls outside the time coverage of this review Casiro et al (1994) found that after a TV campaign on the dangers of alcohol consumption during pregnancy, more women concluded that drinking would put their baby at risk, and attributed this information to TV.

The review identified 7 studies in the area of counter-advertising. All of the studies were carried out in the USA, with the exception of 1, which was a USA/Australia comparative study. A variety of research designs was used, including content analysis, experimental studies, a controlled trial, and a lab test. Student samples were used in 3 of the studies, and high school pupils were also used in 3; the final study used a mixed sample of both students and high-school pupils. As far as target groups were concerned, 1 study dealt with binge drinkers, and 4 included under-age drinkers in the sample. Taken together, the studies generally investigated respondent exposure to, reception of, attitude to, and opinion about counter-advertising in the context of their beliefs, attitudes and behaviour in relation to alcohol and of their media usage. Media used in these studies to carry warnings about alcohol included a simulated promotional t-shirt, a fictitious beer brand bottle label, and television, video and magazine advertising. Generally speaking, there is some evidence to suggest, for example, that the power of counter-advertising on television to affect teenage decision-making concerning alcohol depends on production quality, tight targeting, perceived relevance, realism, similarity, desirability, and identification, as well as on positive messaging; the strength of the counter-advertising statement, and its prominence are also factors; counter-advertising is not seen to be as effective as commercial advertising; commercially sponsored warnings may not have an adverse effect on the perception of the alcohol provider; warning messages which mention less salient risks might promote greater societal welfare than messages currently on packaging. Generally speaking, there is a need for further research. Such research would need to examine the impact and effectiveness of different kinds of pro-social advertising and warnings across the full range of promotional media. It would also need to develop research designs which would take account of how such messages are consumed and interpreted by the specific target groups as they naturally occur within the UK context.

These studies consider the use of mass media marketing to reinforce community awareness of problems created by alcohol use. This approach may be used to prepare the ground for specific interventions (Casswell et al. 1990; Holder and Treno 1997). According to Anderson & Baumberg's (2006) report *Alcohol in Europe*, media advocacy is also used to support a shift in public opinion for policy changes for example of the introduction of standard drinks labelling on all Australian alcohol containers (Stockwell and Single 1997).

A narrative synthesis is employed for this section because of the heterogeneity of studies in this sample. No systematic reviews of counter-advertising interventions or of PSAs were identified. This review therefore comprises individual studies that cover media advocacy-related interventions such as education and public information approaches targeting the behaviour of the individual drinker or mobilising public support for prevention measures (Casswell and Gilmore 1989). It also includes counter-advertising related interventions such as health warning labels on product packaging and media literacy efforts to raise public awareness of the advertising tactics of the alcohol industry, as well as prevention messages in magazines and on TV. Examples of counter-advertising cited by *Alcohol in Europe* involve inclusion in community or school prevention programs (e.g., Giesbrecht et al. 1990; Greenfield and Zimmerman 1993), or as part of the multiple agenda of government spirits board retail systems (Goodstadt and Flynn 1993).

Evidence to date signals a need to manage the balance between public health campaigns and industry advertising in an active and circumspect manner. This includes considering the extent to which industry should take an explicit responsibility for supporting public health messages. It would, for example, be perverse if the industry was to contribute to the content of counter-advertising and yet, at the same time specifically undermine its messages through its own advertising strategies.

## **2.6 Implications for particular policy priority groups**

Details of specific policy priority groups included in research studies can be identified from the following evidence tables, which indicate in the first column of the tables if the study covers one of the priority groups.

### **Underage drinkers**

Studies of the effects of advertising on young person's drinking have been criticized (Thomsen & Rekke 2004) for not being able to provide sufficient empirical support for a causal link between media exposure and attitudes and behaviours (e.g. mentioning Kohn and Smart 1984; Smart 1988). Others are limited as evidence in only being able to report very small effect sizes (Nelson 1999; Strickland 1983). A study predating the review, Aitken et al (1988) did find that TV advertisements in particular have an effect in encouraging underage drinking.

### **Binge drinkers aged 18-24**

Kuo et al (2003) examined the relationship between local alcohol marketing rates (number of bars and liquor stores located near campus) and promotions (like "all you can drink" for one price) and college binge drinking rates. Promotions such as special prices at certain times and sales of high volume containers (kegs and "party balls") were strongly linked with increased heavy drinking. Some commentators have identified methodological problems with this study.

Interestingly, this study also found that binge-drinking rates were elevated when college students were more likely to be "carded" or "proofed" to verify their ages to drink at bars. While the researchers thought this might be explained by greater enforcement efforts in areas with bigger problems, it could support the argument of those who believe that a higher drinking age is likely to increase bingeing. In this scenario, under-age drinkers, fearful of being caught, buy alcohol in larger quantities when they can get it and drink it faster so they

can hide the evidence. Saffer & Dave (2003) identified a modest positive effect of alcohol advertising on binge participation.

### **Low income**

No studies were identified from the advertising research literature specifically examining this particular priority group.

### **Harmful drinkers**

No studies were identified from the advertising research literature specifically examining this particular priority group.

## **2.7 Conclusion**

### **Advertising and promotions in general**

Available evidence suggests that price promotions do increase binge drinking and that exposure to point of purchase advertising predicts the onset of youth drinking. Regardless of their explicit intention there is evidence for an effect of alcohol advertisements on underage drinkers. Consistent with this, evidence suggests that exposure to such interventions as **TV, music videos and billboards**, which contain alcohol advertisements, predicts onset of youth drinking and increased drinking. As a consequence one may conclude that restricting the volume of advertisements and merchandising is likely to reduce consumption and subsequent harm.

Multiple methods and media are currently used to promote alcohol products to different segments of the population in economically developed countries like the UK. Although a number of studies exist about individual types of advertising, the data on which such evidence is based is often less than adequate. Some countries have attempted to ban or restrict some or all categories of alcohol promotion and there is a literature concerning evaluations of the impacts of such bans on both consumption of alcohol and, in some cases, on adverse outcomes such as alcohol-related road trauma.

Evaluating the relationship between expenditure on advertising, restrictions on advertising and alcohol consumption can be complex. Expenditure on alcohol advertising across different media will rise and fall as rival companies perceive an opportunity to exploit a new market or add to their market share. It is extremely difficult in such a situation to measure and model the effects of advertising on alcohol consumption, not least in particular subpopulations. Nonetheless, attempts have been made with mixed results to model these effects.

The link between advertising and consumption is clearest in terms of evidence when read longitudinally. It is also consonant with “social marketing” work on tobacco and food policy/impact, which is having an increasing effect on policy-making. This effect is also attested to by some larger independent surveys with a lower potential for bias.

Against such evidence is ranged a significant body of scholars who attempt to argue that advertising does not increase demand. The affiliation and interests of this group are worthy of closer inspection with evidence of exposure through a somewhat limited range of publishing vehicles. Such opponents of the view that advertising stimulates consumption and has the ability to create growth in alcohol markets persist with the claim that advertising is only about brand switching. Given that providers are continuously seeking to stimulate growth in earnings per share, it is difficult to see how this claim is tenable. Advertising is a key component of marketing strategy to deliver such growth as evidenced by high adspend/turnover ratios.

However, based on the evidence, it is difficult to consider that measures to control the use of specific advertising channels, rather than comprehensive bans, will have a significant impact when compared with other policy options. It is true that advertising may have an aggregative effect but when relatively modest individual effects are taken into account it is clear that

attempts to restrict these may not suffice when they are the mainstay for any policy interventions.

In terms of priority groups, it is well documented that in economically developed countries like the UK, adolescents and young adults receive considerable exposure to alcohol advertising and promotions of different kinds. Studies have explored and measured the extent of alcohol advertising in student newspapers, TV programmes, popular music, point-of-sale promotions, movies approved for young people aged 14 years and over, at sporting events, at concerts, in magazines and placement of alcohol brand names on items owned by young people (Anderson & Baumberg 2006). The use of advertising that highlights low prices is particularly common (Pedersen (2002). One USA study (Jernigan et al, 2004) found that underage youths (ie under 21 years) were substantially more likely to be exposed to alcohol adverts than were those aged 21 years or older suggesting specific targeting by the alcohol industry of underage drinkers. This effect was especially pronounced for females. Furnham et al. (1997) reported that 86% of all episodes of British TV soap operas contained visual or verbal references to alcoholic beverages. There are also studies demonstrating a) heavier drinking young people are more likely to see and appreciate alcohol promotions and b) young people who are more exposed to alcohol advertisements and like them are more likely to be heavy drinkers later in their development (Collins et al, 2007) and/or express greater intention to drink (Pasch et al, 2007). These studies are suggestive of a causal link between advertising and an increase in consumption of young people but do not, on their own, constitute definitive proof.

### **Specific types of promotions**

Several studies have explored more micro- or local-level forms of alcohol promotion such as happy hours or "never-ending" refillable glasses. Price discounting is associated with increased binge drinking (Kuo et al, 2005) but the relationship is complicated by seasonal changes in consumption, such that as demand increases at a particular time of year, competition for customers means that the opportunity to discount prices may be greater as retailers compete to maximise their market share. However, a classic experimental study lends weight to Kuo et al's findings by demonstrating that half price drinks during happy hours increased overall consumption of both occasional and regular drinkers (Babor et al, 1978).

### **Bans and other restrictions**

Studies of complete bans of one or more forms of advertising across different jurisdictions or countries provide clearer opportunities to estimate the effect sizes. However, even these studies can be subject to the confounding effect of the "wetness" or "dryness" of local drinking cultures. For example, advertising bans may be more likely to be implemented in countries after alcohol consumption and related problems have been rising for some years. In other countries, a predominantly "dry" sentiment might encourage both low levels of drinking and high levels of restriction. Arguably, the best studies examine the impact of changes over time in advertising restrictions on local levels of alcohol consumption.

One high-quality meta-analysis covering 132 studies (Gallet, 2007) from a variety of countries, time periods and using different methodologies estimated specific elasticities for changes in advertising expenditure on the expenditure on specific beverages. This analysis showed only very small effects, but the use of aggregate total advertising expenditure to estimate the effects of advertising has been widely criticised.

Studies of the impact of advertising bans or partial restrictions have produced varying estimates of the effect sizes. An earlier systematic review and modelling of the impacts of alcohol policies on alcohol consumption (Chisholm et al, 2004) estimated modest effects of only between 2% and 4% decrease in consumption of alcohol from a complete ban. One USA-based research group found no evidence for advertising bans affecting consumption in analyses of longitudinal data from 45 USA states between 1983 and 1997 (Nelson et al, 2004) and longitudinal data on 17 OECD countries (Nelson and Young, 2001). Another USA-based research group found consistently positive results suggesting the effectiveness of advertising bans on *youth* drinking when studying longitudinal USA survey data (Saffer and Dave, 2003; Saffer and Dave, 2006) as well as economic data from 20 OECD countries

(Saffer and Dave, 2002). Both sets of studies found evidence suggesting advertising bans negatively affect alcohol consumption. Other published analyses of the impacts of advertising bans suggest there are multiple ways of getting around these, as well as the possibility of other unintended consequences such as increased price competition as a means of increasing market share (Tremblay & Okuyama, 2001).

### **Industry Self Regulation**

To date, self-regulation by beverage alcohol industry does not have a good track record for being effective. There is a forthcoming UK report by KPMG, which will describe a detailed investigation of this issue.

### **Counter advertising and public service announcements**

A few studies have explored the potential impact of "counter advertising" which uses various opportunities to provide health and safety messages supposedly to combat the effectiveness of alcohol promotions. The literature suggests that the volume of these in most countries is tiny compared to that of alcohol advertisements, that they are not perceived as effective by consumers nor is there substantive empirical evidence to suggest effectiveness (Gorman, 1995).

### **Summary**

In summary, in saturated alcohol markets such as that in the United Kingdom, drinkers and potential drinkers are exposed to a plethora of alcohol promotions. Young people, and young women in particular, are very likely to be exposed to these, aware of them and there is suggestive evidence that their attitudes towards alcohol and inclinations to drink can be shaped by this exposure. There is increasing evidence that alcohol advertising seen by young people is associated with initiation of drinking and with heavy drinking. Much of the evidence comes in the form of cohort studies from USA, New Zealand and otherwise outside of the UK. However, there is sufficient consistency of effect across a wide range of advertising media to suggest the need for preventative measures. This is particularly the case as those affected by advertising include youths and young people on either side of the regulatory age limits.

There is conflicting evidence as to whether banning alcohol advertising will have significant effects on consumption with some studies suggesting no effects or even positive effects on consumption while others have suggested quite significant reductions in both consumption and related harms. However, there are significant methodological difficulties with conducting these studies. We conclude that a modest effect of alcohol advertising and promotion on alcohol consumption is probable. This is consistent with marketing research concerning other products. Elasticities in the range of 0.02 to 0.04 (Chisholm et al, 2004) and 0.05 and 0.08 (Saffer and Dave, 2003) for the effects of advertising bans are plausible.

There is no evidence to support the effectiveness of self-regulatory codes either as a means of limiting types of advertisements deemed unacceptable or as a means of reducing alcohol consumption.

Evidence of various types supports that local price discounting is highly effective, a conclusion consistent with the large number of studies reviewed in Review 1.

|---|---------------------------|--|--|--|---|--|
| <p>Caswell &amp; Zhang (1998)<br/>New Zealand</p> | <p>Longitudinal study</p> | <p><b>Study Setting:</b> Birth cohort assessed every few years, most of them in their home city of Dunedin, NZ. Questions about alcohol are asked as part of the day-long assessment.<br/><b>Sample at Baseline:</b> 1661 babies born in a Dunedin hospital during 1972. Present analyses draw on data collected from the sample when they were 18 and 21 years and were collected in the years 1990/91 and 1993/94.</p> | <p><b>Study Sample:</b> 921 in phase 18 years old, 942 in phase 21 years. A structural equation model was analysed in the present study with the combined sample size of 630 of those who drank beer at age 18. The selection of beer drinkers for analysis in this study was because the majority of the advertising to which the sample was exposed was for beer.<br/><b>Outcome Measures:</b> Responses to questions to beer consumption, liking for advertising, favourite brand of beer and self-reports of alcohol-related aggressive behaviour.<br/><b>Data analysis:</b> Structural equation modelling</p> | <ul style="list-style-type: none"> <li>● Average volumes of absolute alcohol consumed in the form of beer 13.6 and 20.3 l per person at age 18 and 21 respectively. Medians were 5.9 and 9.5 l, and 95 percentiles were 50 and 77 l per person, respectively.</li> <li>● There are significant paths from liking of advertisements and brand allegiance at age 18 to beer consumption at age 21. However, while brand allegiance at age 18 had a positive impact on beer consumption at age 18 there was no impact of liking for advertising at age 18 on consumption at age 18, nor was there any evidence of hypothesized reciprocal paths from consumption at 18 to liking for advertising and brand allegiance at age 18.</li> <li>● Hypothesized relationship of beer consumption at 18 affecting beer consumption at 21 significant but small relative to other relationships in model.</li> </ul> | <p>Three items assessing people's experience of problems associated with aggression were used in the present analyses. These were: "being told to leave a place because of your drinking"; "got into a physical fight because of your drinking"; "been involved in a serious argument after you have been drinking". The proportions of the sample responding that they had experienced each of these were 16%, 23% and 30% respectively.</p> | <p><b>Limitations:</b></p> <ul style="list-style-type: none"> <li>● Self-reported data on alcohol-related aggressive behaviour.</li> <li>● Generalizability? – at time of data collection, minimum legal drinking age in NZ age 20.</li> </ul> <p><b>Reported conclusions (by authors):</b></p> <ul style="list-style-type: none"> <li>● The volume of beer consumed at age 21 was significantly influenced by all the three variables measured at age 18: volume of beer consumed; liking for alcohol advertising and brand allegiance. Of these brand allegiance and liking of advertising had stronger impacts on the volume consumed at age 21 than did the volume of beer consumed at age 18, and liking for advertising had the strongest relationship: a standardized coefficient of 0.36.</li> <li>● The relationship between brand allegiance and volumes consumed was present at both ages 18 and 21. The results showed that having a preference for a specific brand, and also having a preference for the brands of which the imagery was in keeping with the traditional Kiwi values of masculinity and hard physical activity, were associated with the consumption of larger volumes.</li> <li>● Liking of advertisements not associated with volumes of alcohol consumed at time it was measured, when sample was aged 18, but did have a significant impact on drinking levels measured 3 years later.</li> <li>● Gender was a significant variable. Men liked the advertising more and were also independently more likely to consume large amounts, more so at age 21 than at age 18. There was however no direct effect of gender on reports of aggression; this appeared to be mediated entirely through the effects on consumption levels.</li> <li>● Strong relationship between volume consumed at age 21 and experience of aggression associated with drinking.</li> </ul> |
|---|---------------------------|--|--|--|---|--|

|  |  |  |   |  |  |  |
|--|--|--|---|--|--|--|
|  |  |  | <ul style="list-style-type: none"><li>● Relationship between beer consumption and experience of alcohol-related aggression was also significant.</li><li>● Gender found to be significantly related to liking for advertising and beer consumption at both 18 and 21.</li></ul> |  |  |  |

|---|--------------------------|--|--|---|---|
| <p>McCreanor et al (2005)<br/>New Zealand</p> | <p>Qualitative study</p> | <p><b>Study Setting:</b><br/>Young people in Auckland recruited from community networks of research team. Data recorded "since early 2003" (paper received Sept. 2005).</p> <p><b>Sample at Baseline:</b><br/>"...more than 250 young men and women aged between 14 and 18 years..."</p> | <p><b>Study Sample:</b><br/>Focus groups from event-related (e.g. social events such as concerts, parties, school balls etc.) and affinity-group (e.g. groups of 3-5 friends matched by age, ethnicity and gender) sessions.</p> <p>Sample included both indigenous Maori and settler non-Maori settler peoples, usually of European descent.</p> <p><b>Outcome Measures:</b></p> <ul style="list-style-type: none"> <li>▪ Engagement (ability to recognise, discuss, debate and elaborate – with meanings round alcohol marketing).</li> <li>▪ Identification</li> <li>▪ Consuming identities (of alcohol marketing)</li> </ul> <p><b>Data analysis:</b> Describes series of themes running through participants' talk on the topic of alcohol.</p> | <p><b>Engagement:</b></p> <ul style="list-style-type: none"> <li>▪ Many participants commented on specific advertisements and campaigns that demonstrate both awareness of the product and a reflexive understanding of the milieu.</li> <li>▪ Multiple ways in which different ad campaigns (Tui, Export, Steinlager, Export Gold in the example given) merge and morph in relation to each other suggests an overall effect of congruence rather than dissonance in terms of the ways in which the participants engage with the marketing and with any one of these brands.</li> <li>▪ Overall participants actively engaged with marketing materials and often articulated sophisticated understandings of youth cultures that explained the interweaving of social and symbolic aspects of markets with youth identities.</li> </ul> <p><b>Identification:</b></p> <ul style="list-style-type: none"> <li>▪ Participants very aware of importance and power of consumption in young people's lives, arguing that engagement in buying and possessing provides salient and interesting markers to signal identity, status and belonging.</li> <li>▪ Overall, participants demonstrate identification with marketing and brands at both social and personal levels, understand themselves to be targets of campaigns, and value knowledge and scenarios from specific advertisements as accurate representations of youth interests and cultures.</li> <li>▪ Some participants' analyses work critically and reflexively with alcohol marketing in particular highlighting the targeting of young people through a range of approaches and content.</li> </ul> <p><b>Consuming Identities:</b></p> <ul style="list-style-type: none"> <li>▪ Engagement and identification enable personification of branded products and uptake of such alcohol identities.</li> <li>▪ Participants demonstrate varied ways in which alcohol identities are taken up and made use of in personal and social settings. These include playful use of identity positions and unwanted attributions of others.</li> </ul> | <p><b>Limitations:</b></p> <ul style="list-style-type: none"> <li>▪ Convenience sample.</li> <li>▪ Baseline sample not clear.</li> <li>▪ Limited detail on methods.</li> <li>▪ Timeframe not clearly defined.</li> </ul> <p><b>Comments:</b></p> <ul style="list-style-type: none"> <li>▪ National alcohol surveys in NZ have shown increased youth consumption with young people drinking more frequently, increasing quantities they drink on a typical drinking occasion, increasing their number of heavier drinking occasions.</li> <li>▪ Focus groups were open-ended interviews about social life guided by means of a broad interview guide that included a number of leads toward discussing alcohol marketing, including:             <ul style="list-style-type: none"> <li>▪ What events have you been to lately?</li> <li>▪ What is cool?</li> <li>▪ What are your favourite ads?</li> <li>▪ If you were a drink, what would you be?</li> <li>▪ What do you do in the weekends?</li> </ul> </li> </ul> <p><b>Reported conclusions (by authors):</b></p> <ul style="list-style-type: none"> <li>▪ Findings are highly congruent with strong international evidence of over-exposure of young people particularly in youth-orientated media. Familiarity and level of comfort with alcohol brands demonstrate that success of these marketing styles is strongly contributing to this goal.</li> </ul> |
|---|--------------------------|--|--|---|---|

|  |                        |  |   |  |   |
|--|------------------------|--|---|--|---|
| <p>Nelson &amp; Moran (1995)<br/>USA</p> | <p>Empirical study</p> | <p><b>Study Setting:</b> USA consumption and advertising data.</p> | <p><b>Study Sample:</b><br/>Annual USA data for 1964-1990 on beverage consumption, prices, expenditures, and real advertising.</p> <p><b>Outcome Measures:</b><br/>Conditional demand for US alcoholic beverages.<br/>Advertising and conditional demand by beverage.<br/>Advertising and composite demand for ethanol.</p> <p><b>Data analysis:</b><br/>Four differential demand models.</p> | <ul style="list-style-type: none"> <li>In all four models, advertising coefficients for wine are positive and statistically significant. Additionally, wine advertising has statistically negative effect on spirits demand, while spirits advertising has statistically negative effect on wine demand.</li> <li>Advertising elasticities are small in magnitude, 0.1 or less in absolute value. This indicates that advertising does not have a very strong effect on alcohol demand at the beverage level. E.g. 1% increase in the growth of real advertising of wine increases consumption of wine by only 0.1% and reduces spirits consumption by only 0.03%. Thus, results support the FTC's (Federal Trade Commission) view of alcohol advertising: that is, while advertising of alcoholic beverages may influence choice of brand, there is very little impact on beverage demand.</li> </ul> | <p><b>Limitations:</b><br/>No specific limitations found.</p> <p><b>Comments:</b></p> <ul style="list-style-type: none"> <li>Supports general view advertising has little impact (at the margin) on demand for beverages, and instead serves to alter brand shares. Further, beer demand is always independent of advertising of other beverages.</li> </ul> <p>Confirms earlier results obtained for UK by Duffy (1987, 1990) and Selvanathan (1989a). For USA, results for beer demand obtained by Lee and Tremblay (1992) also strongly supported.</p> <p><b>Reported conclusions (by authors):</b><br/>Alcohol advertising has no effect on consumption of total ethanol and very small effects on consumption of individual beverages.</p> |

|   |  |   |  |   |  |  |
|---|--|---|--|---|--|--|
| <p>Ofcom (2007)</p> <p>UK</p> <p>Under age drinkers</p> | <p><b>Design</b><br/>Qualitative &amp; quantitative research.</p> <p>Qualitative – 11 discussions groups across the UK.</p> <p>Quantitative – Interviews. Additionally, Ofcom conducted analysis to look at changes in advertising trends based on Nielsen Media data.</p> | <p><b>Study Setting</b><br/>UK</p> <p><b>Sample at Baseline</b><br/>Representative sample of 1,514 young people aged 11-21 across the UK.</p> | <p><b>Study Sample</b><br/>11-21 year olds across the UK.</p> <p><b>Outcome Measures</b><br/>Recall of advertising, likeability, whether young people thought adverts were aimed at them, if commercial made drink look appealing &amp; if it would encourage people to drink.</p> <p>Changes in advertising trends based on Nielsen Media data.</p> <p><b>Data analysis</b><br/>Statistical analysis was conducted.</p> | <p>Proportion of 11-13 years who had never drunk alcohol has increased from 31% in 2005 to 46% in 2007.</p> <p>Alcopops have declined in popularity.</p> <p>There has been an increase in the amount of cider young people report drinking.</p> | <p>Recall in alcohol advertising declined between 2 waves of research.</p> <p>Significant decline in average number of unprompted mention of alcohol adverts from 3.95 to 3.31. From 2005 - 7 there was a decline in recall of beer (76% to 69%), alcopops (50% to 42%), vodka (20% to 16%) &amp; spirits (17% to 7%) advertising &amp; increase in recall of cider (6% to 19%) advertising. With the exception of vodka the downward shift in TV advertising spend was matched by a downward shift in advertising recall. For cider increase in spend was matched by increase in recall. Most changes in recall are mirrored by change in advertising spend.</p> <p>The likeability of adverts has remained almost exactly the same between the 2 waves of research Young people are less likely to feel that the adverts are aimed at them (net agreement score has fallen from 7% to -13%). However, young people are more likely to say that the adverts make the drink look appealing (net agreement score has increased from 25% to -34%) &amp; they will encourage people to drink (net agreement score has increased from 24% to 28%).</p> | <p><b>Limitations</b></p> <ul style="list-style-type: none"> <li>• Due to multi-faceted relationship between young people &amp; alcohol, is limited in understanding impact of regulatory changes.</li> <li>• Alcohol advertising market, when post wave research was conducted, is different to that researched in the pre wave (2005). There is now considerably less exposure to alcohol advertising on TV amongst young people in 2007 compared with 2005 &amp; types of products being advertised are markedly different – so the pre &amp; post wave studies are not directly comparable.</li> <li>• Changes in alcohol advertising market &amp; cultural changes which have taken place between this and the earlier study cannot be conclusively attributed to changes in the advertising code.</li> <li>• Adverts used were not a random selection &amp; as are not representative of all adverts in the category. Adverts were selected on how appealing adverts they were thought to be to young people &amp; how appealing the actual products were thought to be to young people.</li> </ul> <p><b>Comments</b></p> <ul style="list-style-type: none"> <li>• Measures extent to which changes to alcohol advertising rules made in 2005 may have impacted on appeal of selection of alcohol advertisements to people under age of 18. The baseline report (Ofcom, 2005) is discussed above</li> <li>• Specifically deals with Advertising Standards Code changes to TV advertising of alcohol.</li> <li>• Strength was that random location sampling technique used to ensure a representative sample of 11-21 year olds in UK. Quotas were set on age and gender &amp; for those over 16 on working status. At the analysis stage, data weighted to ensure that final sample was representative of UK.</li> </ul> <p><b>Reported conclusions (by authors).</b></p> |
|---|--|---|--|---|--|--|

|  |  |  |  |  |  |  |
|--|--|--|--|--|--|--|
|  |  |  |  |  |  | <ul style="list-style-type: none"> <li>• In 2005 when Advertising Code changes were introduced it was felt necessary to provide a benchmark by which the appeal of future commercials would be measured.</li> <li>• Considerable market and cultural changes since introduction of code changes in 2005 &amp; between the 2 waves of research mean that the 2 waves are not directly comparable and it would be difficult to untangle impact of these changes on young people's attitudes &amp; behaviour towards both alcohol &amp; alcohol advertising.</li> <li>• Alcohol advertising market has changed significantly, particularly with regards to TV advertising. TV alcohol advertising spend has declined &amp; young people are exposed to less TV advertising for alcohol products.</li> <li>• The recall of alcohol advertising has declined since 2005 &amp; is most probably linked to this decline in advertising spend.</li> <li>• There has been no change in how many young people say they like the adverts but there has been an increase in those saying the adverts make the drinks look appealing &amp; would encourage people to drink it.</li> <li>• Importantly, however, given objectives of the Advertising Code changes, there has been a decline in the proportion of young people saying they feel commercials are aimed at them.</li> </ul> |

|   |                                 |   |  |  |   |
|---|---------------------------------|---|--|--|---|
| <p>Robinson et al (1998)<br/>USA<br/>Underage</p> | <p>Prospective cohort study</p> | <p><b>Study Setting:</b> Six public high schools in San Jose, California<br/><b>Sample at Baseline:</b> Of 3194 ninth-grade students, 2777 were eligible to participate. A total of 2609 eligible students (94.0%) participated in baseline assessment.</p> | <p><b>Study Sample:</b> Of participating students at baseline, 1583 (61.0%) also participated in follow-up assessments 18 months later. 75 students excluded from analysis because of inconsistent responses on reports of alcohol use. Analysis include 1533 students; mean age = 14.6 years.<br/><b>Outcome Measures:</b> Students reported hours of TV, music video, and videotape viewing; computer and video game use; and lifetime and past 30 days' alcohol use at baseline and 18 months later.<br/><b>Data analysis:</b> Associations between baseline media exposure and subsequent alcohol use were examined with multiple logistic regression.</p> | <p>During the 18-month follow-up, 36.2% of baseline nondrinkers began drinking and 50.7% of baseline drinkers continued to drink. Onset of drinking was significantly associated with baseline hours of TV viewing (odds ratio [OR] = 1.09; 95% confidence interval [95% CI] = 1.01-1.18), music video viewing (OR = 1.31; 95% CI = 1.17-1.47), and videotape viewing (OR = 0.89; 95% CI = 0.79-0.99), controlling for age, sex, ethnicity, and other media use. Computer and video game use was not significantly associated with the subsequent onset of drinking. Among baseline drinkers, there were no significant associations between baseline media use and maintenance of drinking.</p> | <p><b>Limitations:</b></p> <ul style="list-style-type: none"> <li>● Study involved students from six public high schools in a single urban area.</li> <li>● Students not attending school, not eligible, or lost to follow-up are not included in the sample.</li> <li>● Although sample was ethnically and socioeconomically diverse, generalization of results beyond study population is always cautioned.</li> <li>● It is possible for attrition to introduce biases. As is typical in school-based samples, dropouts tended to represent a higher-risk group than did students remaining in the sample. However, losing these high-risk adolescents from the sample would be expected to reduce the magnitude of the associations between media exposure and alcohol use, not exaggerate them.</li> <li>● Data limited to self-reports and cannot rule out possibility that measurement error influenced results.</li> <li>● Study did not assess other established risk factors for alcohol use or the specific media content to which adolescents were exposed.</li> </ul> <p><b>Comments:</b></p> <ul style="list-style-type: none"> <li>● Strength of association between TV and music video exposures and subsequent onset of alcohol use was found to be quite large. One extra hour of TV viewing per day was associated with an average 9% increase in risk of starting to drink over next 18 months. Similarly, 1 extra hour of music video viewing per day was associated with an average 31% increase in risk of starting to drink over next 18 months.</li> <li>● Results consistent with previous research.</li> <li>● Alternative explanation is that higher-risk adolescents – those predisposed to become future</li> </ul> |
|---|---------------------------------|---|--|--|---|

|  |  |  |  |  |
|--|--|--|--|--|
|  |  |  |  | <p>drinkers – are also those who are more attracted to TV and music videos. Music video viewing was cross-sectionally associated with an index of multiple risky behaviors, including alcohol use, in a large sample of adolescents in Southeastern USA).</p> <ul style="list-style-type: none"> <li>● This may be explain inverse associations between VCR video viewing and onset of alcohol use. Spending more time watching videos in a VCR, to some extent, may be a proxy for generally low-risk adolescents. However, this explanation is not consistent with the finding that greater TV and music video viewing is associated with initial onset of alcohol use but not with continued use.</li> <li>● To maximize validity of self-reports, used well-established, previously validated measures of alcohol use, and made extensive efforts to assure confidentiality.</li> </ul> <p><b>Reported conclusions (by authors):</b></p> <ul style="list-style-type: none"> <li>● TV and music video viewing are independent risk factors for the onset of alcohol use in adolescents. In contrast, adolescents who spend more time watching videos in a VCR are at lower risk of starting to drink alcohol. In addition media use appears to influence onset of drinking but not continued alcohol use.</li> <li>● Although causal inferences cannot be drawn from nonexperimental study, several criteria have been suggested to help judge whether epidemiologic risk factor may be causally related to a specific outcome. They include temporal sequence, strength of the association, exposure response, specificity, consistency, experimental evidence, and plausibility and coherence.</li> <li>● Exposure to portrayals and promotion of alcohol use in the media may be causally linked to the onset of adolescent drinking.</li> </ul> |

|--|---------------------------|--|---|--|---|
| <p>Saffer, H. &amp; Dave, D. 2006<br/>USA</p> <p>Underage<br/>Binge Drinkers</p> | <p>Longitudinal study</p> | <p><b>Setting</b><br/>Uses data from monitoring the Future (MTF) and National Longitudinal Survey of Youth, 1997 (NLSY97) and looks at effect of reduction in alcohol advertising.</p> <p><b>Baseline sample</b></p> | <p><b>Study Sample</b><br/>Special version of MTF data that merged advertising &amp; price was made available to study. Merged data set contained only a limited set of individual-specific variables.<br/>MTF data are a pool of 1996 and 1998 cross-section of 8<sup>th</sup>, 10<sup>th</sup> &amp; 12<sup>th</sup> graders. This pool is a nationally representative sample of over 63000 high school students. Pooling of the 1996 &amp; 1998 surveys provides sufficient samples for separate analyses of the effects of price &amp; advertising by race &amp; gender. Pooling these 2 years also provides additional time variance, especially in the alcohol advertising &amp; price measures.</p> <p>NLSY97- sample consists of approx 10000 youths were 12-16 as of 31/12/1996.<br/>NLSY97 is representative of adolescents nationwide and provides important alternative to MTF by including individuals not in school &amp; data from parents.</p> <p>Advertising data obtained from Competitive Media Reporting (CMR) which collects advertising data in</p> | <p>Price and advertising effects are generally larger for females relative to males. Controls for individual heterogeneity yield larger advertising effects, implying that the MTF results may understate the effects of alcohol advertising.</p> <p>Results from the NLSY97 suggest that a 28% reduction in alcohol advertising would reduce adolescent monthly alcohol participation from 25% to between 24 and 21%. For binge participation, the reduction would be from 12% to between 11 and 8%. The past month price participation elasticity is estimated at -0.26.</p> | <p><b>Limitations</b></p> <ul style="list-style-type: none"> <li>• Used self-report data for alcohol consumption.</li> <li>• Findings relevant to USA population but may not be generalisable to other population or geographic locations.</li> <li>• Focused on participation only as easier for respondent to measure if drank compared to how much.</li> <li>• Data analysed is for adolescents 10 years ago who could be significantly different to today's adolescents.</li> <li>• Data set used is limited to 75 largest cities in USA.</li> </ul> <p><b>Comments</b></p> <ul style="list-style-type: none"> <li>• Large sample of MTF allows estimation of race &amp; gender specific models.</li> <li>• Longitudinal nature of the NLSY97 allows controls for unobserved heterogeneity with state-level &amp; individual fixed effects.</li> <li>• The past month price-participation elasticity is estimated at -0.26, consistent with prior studies.</li> <li>• Reliability of CMR data is widely recognised in the advertising industry. All of the data reported are independent estimates &amp; do not use any info from alcohol producers.</li> <li>• Weighted means are provide for MTF &amp; NLSY97 for all relevant variables.</li> </ul> <p><b>Reported conclusions (by authors).</b></p> <ul style="list-style-type: none"> <li>• Reduction of alcohol advertising can produce a modest decline in adolescent alcohol consumption, though effects may vary by race and gender.</li> <li>• Complete elimination of all alcohol advertising with restriction on additional expenditures on other marketing techniques, or the elimination of all forms of alcohol marketing, would undoubtedly result in further decreases in monthly alcohol</li> </ul> |

Alcohol advertising promotes and reinforces the use of alcohol with range of activities that teenagers aspire to, engage in and enjoy. For young people 'selling aspects of alcohol advertisements relate to linking alcohol to positive images of desirable lifestyles and little to do with selling the actual alcohol product advertised.</li> <li>• Alcohol advertising is likely to have a greater impact among younger age groups and 15-17 year old girls than older boys.</li> <li>• Alcohol advertisements infringe Irish alcohol advertising code in several ways.</li> <li>• Alcohol advertising in broadcast media is just one aspect of a marketing mix that includes radio, print media, billboards, sponsorships and alcohol branded products.</li> <li>• Young people have high exposure to recurring positive messages about alcohol, which over time, help to create or reinforce attitudes &amp; beliefs and can influence intention and subsequent drinking pattern.</li> </ul> | <p><b>Beliefs about alcohol</b><br/>Twice as many negative beliefs as positive beliefs expressed in younger age groups, but a similar amount of positive &amp; negative beliefs expressed in the older age groups. The number of positive beliefs expressed was similar in both age groups for both genders, the amount of negative beliefs expressed was significantly less in the older age groups.</p> <p>Most positive beliefs about alcohol concerned mood or feelings. Most often mentioned belief common to all groups was that 'having fun' was a key benefit of alcohol use. This belief was particularly strong amongst the older girls.</p> <p>Negative beliefs tended to be about behavioural or physical effects (e.g. hangovers, causes accidents, get into fights). Older boys had fewest negative beliefs of all groups.</p> | <p><b>Favourite advertisements</b><br/>Alcohol advertisements were by far the favourite among the participants.</p> | <p><b>Appeal of adverts</b><br/>Humour was the most popular ingredients or all of the groups. Other devices that appealed included animation, music, use of a sports personality, and use of animals, babies or objects with visual appeal.<br/>Adverts containing more than 1 element of appeal were among the most popular.</p> |

|---|------------------------|---|---|---|---|
| <p>Nelson &amp; Young (2001)<br/>Comparison of 17 OECD countries.</p> | <p>Empirical study</p> | <p><b>Study Setting:</b> 17 OECD countries for the years 1977-1995: Australia, Austria, Belgium, Canada, Denmark, Finland, France, Ireland, Italy, Luxembourg, the Netherlands, Norway, Portugal, Spain, Sweden, the <b>United Kingdom</b>, the United States.<br/><br/><b>Sample at Baseline:</b> Average population in 1995 was 32 million, with a standard deviation of 62 million. This includes Luxembourg and USA which might be outliers, and regression results are reported with these countries excluded.</p> | <p><b>Study Sample:</b><br/>As baseline.<br/><br/><b>Outcome Measures:</b></p> <ul style="list-style-type: none"> <li>▪ Alcohol consumption</li> <li>▪ Alcohol abuse</li> <li>▪ Cirrhosis mortality rate</li> <li>▪ Road fatality rate</li> <li>▪ Price growth (all in relation to advertising bans)</li> </ul> <p><b>Data analysis:</b> Regression, log-linear and logit models.</p> | <ul style="list-style-type: none"> <li>▪ Alcohol consumption is positively affected by per capita income, tourism, and measure of drinking sentiment.</li> <li>▪ Alcohol consumption is negatively affected by the real price of alcohol and the percentage of elderly population.</li> <li>▪ The unemployment rate is statistically insignificant.</li> <li>▪ The advertising ban variables are statistically significant in some specifications, but not in others. When the ban variables are significant, regression coefficient signs are positive, which indicates that advertising bans are associated with increased consumption of alcohol.</li> <li>▪ Cirrhosis mortality: estimates indicate positive relationship with income and drinking sentiment, and a negative relationship with alcohol price, elderly population, and the unemployment rate. The advertising ban variables are never statistically significant.</li> <li>▪ Motor vehicle fatalities: positively affected by income and youth population, and negatively affected by elderly population and the unemployment rate. The advertising ban variables, when they have significant coefficients, have positive signs.</li> </ul> | <p><b>Limitations:</b></p> <ul style="list-style-type: none"> <li>▪ Isolating effects of advertising is difficult empirically due to complexity of alcohol control policies in various countries, including public ownership of production and retailing, varying tax rates on alcohol, and strict laws on drink-driving. Because it is not possible to control directly for these differences, it may be incorrect to regard advertising ban variables, especially those for Scandinavian countries, as measuring restrictive policies on advertising exclusively. However, these other policies should bias results towards significantly negative coefficients, which is not found in this study.</li> </ul> <p><b>Comments:</b></p> <ul style="list-style-type: none"> <li>▪ Results consistent with literature, including previous cross-country studies of advertising bans (Young 1993, Calfe &amp; Schergara 1994, Calfee 1997), studies of partial bans of billboard displays, studies of temporary bans, and other long-standing bans of most media, and studies of advertising expenditures using annual and quarterly data.</li> <li>▪ Included two demographic variables and the unemployment rate as controls, omitted from previous studies. The demographic variables are always</li> </ul> |
|---|------------------------|---|---|---|---|

|  |  |  |  |  |   |
|--|--|--|--|--|---|
|  |  |  |  |  | <p>statistically significant. Unemployment rate and youth variables are especially important for motor vehicle fatalities. Estimates obtained in earlier studies may suffer from omitted variable bias.</p> <p><b>Reported conclusions (by authors):</b></p> <ul style="list-style-type: none"> <li>▪ Does not support notion that bans of broadcast advertising of alcoholic beverages reduce consumption or alcohol abuse.</li> <li>▪ A complete ban on broadcast advertising of all beverages has no effect on consumption relative to countries that do not ban broadcast advertising.</li> <li>▪ Fails to provide evidence that advertising bans do not have significant negative effects on alcohol abuse outcomes, including cirrhosis mortality and road fatalities. Suggests ad bans do not have large impact on drinking, although bans may affect brand and beverage choices.</li> <li>▪ Despite long-standing use of adv. bans in many countries, other economic and cultural factors may be more important as determinants of drinking patterns and consumption.</li> <li>▪ Alcohol price consistently negatively related to consumption and abuse. Supports economic model of ad bans and consumption.</li> </ul> |

|---|--|--|--|---|--|
| <p>Garretson &amp; Burton (1998)</p> <p>USA</p> <p>Underage</p> <p>NB – this study is also included in the sales promotion evidence tables.</p> <p>Counter-advertising outcomes only appear here.</p> | <p>Between-subjects study</p> <p><b>Study Setting:</b> A high school and a university, both in southeastern part of USA.</p> <p><b>Sample at Baseline:</b> 267 respondents (133 under and 134 over the legal drinking age)</p> | <p><b>Study Sample:</b> Sample of university students consisted primarily of senior-level students enrolled in business classes. This sample restricted to respondents who met or exceeded the state's legal drinking age of 21 years. 96% of this sample were between ages of 21 and 30. Mean age = 22.8 years. Median age = 22.0 years.</p> <p>Underage sample consisted primarily of sophomore and junior-level high school students. Ages ranged from 15 to 18 years and the mean and median ages both were 16.0 years.</p> <p>Of total sample approx three-fifths of the sample were men (61%), and the gender percentages did not differ across the high school and college samples (chi-square &lt;1.0, df = 1, ns).</p> <p><b>Outcome Measures (counter-advertising only):</b> attitudes to warning messages (communicated on a simulated promotional T-shirt)</p> <p><b>Data analysis:</b> MANOVAs with follow-up univariate tests.</p> | <p>Univariate results indicate that these two age groups hold different views about many aspects of the perceived risks associated with the consumption of alcoholic beverages. Those under the legal drinking age believe that the use of alcohol poses greater risks than do those over the legal drinking age (marginal means for under-age and above-age consumers are 4.5 and 3.7 respectively.</p> | <ul style="list-style-type: none"> <li>Means, multivariate and univariate interaction and main effect results indicate that inclusion of a warning on the item does not affect attitudes toward the item, the brand or alcohol in general.</li> <li>The warning manipulation affected subjects' perceptions of the beverage marketer's social concern (<math>F = 12.16</math>; <math>\eta^2 = .08</math>; <math>p &lt; .01</math>). When the beverage marketer is identified as the sponsor of the message, perceptions of the beverage marketer's social concern are significantly more favourable than for either the government-sponsored control or the control in which no warning is included (<math>t</math>-values <math>&gt; 2.6</math>, <math>p &lt; .01</math>, for each). However, means are not high for most of these conditions.</li> <li>Although there are some univariate differences in effect of various warning conditions on consumers' perceptions of risk, the overall multivariate effect is nonsignificant. Two results relating to the warning manipulation seem particularly striking. First, risk-related means for the control condition in which there is no warning tend to be as high as the means for conditions in which warning information is included. Second, many of these means are quite high, and for risks of drinking when pregnant or driving after five drinks, several of the cells are equal to or approach the theoretical maximum of the scale. In general,</li> </ul> | <p><b>Limitations:</b></p> <ul style="list-style-type: none"> <li>USA legal drinking age 21 years. Although in underage sample ages ranged from 15-18 years, so possibly comparable.</li> <li>Underage high school students and legal-college age students from single city in southeastern USA used as subjects. Results might not extend beyond this specific sample.</li> <li>Manipulations used in the study were based on both existing warning regulations and a comparison of what brand information presently can be included on a sales promotion item versus what could be included under recently proposed alcoholic beverage legislation. Findings might not extend beyond the specific warnings, brand manipulations, and treatment exposure conditions used.</li> <li>Stimulus was a sales promotion item (t-shirt). Results should be interpreted only in context of this promotional domain, because they might not extend to other promotion types (e.g. advertising).</li> </ul> <p><b>Comments:</b></p> <ul style="list-style-type: none"> <li>Findings regarding brand and item important for alcohol beverage marketers because they show that, if a warning is included, it would not have a negative carryover effect on either the sales promotion item or consumers' overall brand attitudes.</li> <li>There were significant interactions between brand information and age group for the attitude and believability of the warning message. Because the legal-age college students reacted more favourably toward the message when it appeared with the brand and the character, perhaps warning information on college campuses should include such characters.</li> </ul> |

|  |  |  |  | <p>the levels of these means are significantly higher than the scale midpoint, which suggests that the risks of driving after drinking and drinking when pregnant are well known.</p> | <p><b>Reported conclusions (by authors):</b></p> <ul style="list-style-type: none"> <li>Results of warning message manipulation indicate that risks associated with drinking and driving during pregnancy are well-known. Effects of warnings also did not differ across the over- and under-legal-age consumers. Because messages that convey these two risks have appeared on alcoholic beverage containers for the past eight years, consumers arguably might perceive these risks to be high because this information is no longer new. At least for this sample of both under- and over-legal-age consumers, it seems as though the objective of communicating these risks have been achieved.</li> <li>On basis of results, authors argue that in terms of knowledge and attitudes, there is little to be gained from continuation of these two particular warnings (drinking and driving and drinking while pregnant).</li> <li>Suggests that warning messages that communicate lesser-known risks associated with the consumption of alcohol (e.g. immediate risks of addiction and combining drugs with alcohol, the long-term risks of liver disease and cancer) might provide greater benefit to consumer welfare than the messages currently on packaging. The use of rotating warning labels that convey both immediate and long-term risks, for example, might offer an effective means to communicate lesser-believed risks. Promotional items also offer an additional outlet for informing the public about the risks, and warning messages on these items might complement the mandated warnings that now appear on beverage containers.</li> <li>Another important implication pertains to the</li> </ul> |

## Review 3: The effect of alcohol consumption on alcohol related harm

### 3.1 Alcohol consumption and health consequences

Alcohol consumption is related to a wide variety of negative health outcomes including morbidity, mortality, and disability (Rehm et al. 2003). Research on alcohol-related morbidity and mortality takes into account the varying effects of overall alcohol consumption and different drinking patterns. The results from this epidemiological research indicate that alcohol use increases the risk for many chronic health consequences (e.g., diseases) and acute consequences (e.g., traffic crashes), but a certain pattern of regular light-to-moderate drinking may have beneficial effects on coronary heart disease. Gutjahr and Gmel (2001) examined three major social cost studies to produce a state of the art list of alcohol-related fatal medical conditions for which causal evidence exists. This list has been fairly stable over the ensuing decade and a broad general consensus exists regarding both long-term conditions and acute effects. The evidence is more equivocal, however, where it relates to the optimal and harmful levels of consumption and the duration of exposure for irreversible harm to be effected.

The overview by Rehm et al (2003) used published meta-analyses to establish the relationship of alcohol consumption to burden of disease for over 60 conditions. The following review seeks to add the findings from systematic reviews and meta-analyses conducted from 2001 onwards to those from this previous review.

The emphasis is on examining whether findings from this previous review have been confirmed, strengthened or possibly overturned. This review examines the nature of possible causative links between consumption and harm. It should therefore be read in conjunction with Review 1 and Review 2, which attempt to link pricing and promotion to consumption and to establish a direct link between pricing/promotion and harm.

**Table 14 Disease conditions that are by definition alcohol-related (Alcohol-attributable fraction = 1) and recent meta-analytic findings**

| ICD-9        | Disease                            | Meta-analysis            | Findings   |
|--------------|------------------------------------|--------------------------|--|
| 291          | Alcoholic psychoses                | NA                       | NA   |
| 303          | Alcohol dependence syndrome        | Cargiulo (2007)          | Consistent and substantial comorbidity between alcohol dependence and other psychiatric conditions especially mood and anxiety disorders and drug abuse.   |
| 305.0        | Alcohol abuse                      | NA                       | NA   |
| 357.5        | Alcoholic polyneuropathy           | NA                       | NA   |
| 425.5        | Alcoholic cardiomyopathy           | NA                       | NA   |
| 535.3        | Alcoholic gastritis                | NA                       | NA   |
| 571.0        | Alcoholic fatty liver              | NA                       | NA   |
| 571.1        | Acute alcoholic hepatitis          | Li (2008)                | Observed in chronic alcoholics (with or without noticeable liver impairments) and in moderate drinkers after a binge.  |
| 571.2        | Alcoholic cirrhosis of liver       | NA                       | NA   |
| 571.3        | Alcoholic liver damage, unspecific | Li (2008)                | Risk of future liver disease increased significantly for men who consumed 28-41 drinks per week and for women who consumed 14-27 drinks per week.  |
| 655.4        | Foetal alcohol syndrome            | Eustace et al (2003)     | Consumption of alcohol during pregnancy can harm foetus irreparably. Consumption of 7 standard drinks per week may be threshold for most sensitive neurobehavioral changes but not all women and infants are affected equally.                                   |
|              |                                    | Henderson et al, (2007b) | No convincing effects of binge drinking on a range of adverse outcomes including fetal alcohol syndrome and neurodevelopmental effects. Possible effect on neurodevelopmental outcome but further research required. Many studies had methodological weaknesses. |
| 790.3        | Excess blood alcohol               | NA                       | NA   |

| Rows in bold indicate conditions for which the recent literature has been consistent in concluding sufficient evidence for a causal relationship (Rehm et al, 2003). |              |   |                         |   |

### Acute conditions where alcohol is a contributory cause

With respect to acute conditions, most researchers agree on causality (but see Gmel & Rehm 2003) and the conditions listed in Table 15 are traditionally included.

**Table 16 Acute conditions with alcohol as a contributory factor**

| <i>Condition</i>                              | <i>Meta-analysis</i>  | <i>Findings</i>   |
|---|-----------------------|---|
| Injuries from falls (E880-888)                | Borges et al (2006)   | Estimated pooled relative risk for those reporting alcohol use within 6 hours prior to injury was 5.69 (95% CI = 4.04-8.00). However no UK data included. |
|   | Corrao et al (2004)   | Direct trend in risk starting from 25g/day (RR= 1.12 (1.06-1.18)  |
| Fires (E890-899)                              | Taylor & Rehm (2006)  | Interaction of smoking and alcohol may increase risk for fire injury. Not many high quality studies due to low sample sizes.                              |
| Excessive cold (E901);                        | NA                    | NA  |
| Drowning (E910);                              | NA                    | NA  |
| Occupational and machine injuries (E919-920); | NA                    | NA  |
| Suicide (E950-959);                           | Cargiulo (2007)       | Alcohol dependence associated with increased risks of suicide (OR 2.13 95% CI 1.18-3.85) and suicide attempts (OR 2.50 95% CI 1.38-4.52)                  |
|   | Norström et al (2005) |   |
|   | Wilcox et al (2004)   | Overall SMR for heavy drinking was 351 (95% CI 251-478) while it was 39 (95% CI 5-140) for males  |
| Assault (E960-966, E968)                      | Corrao et al (2004)   | Direct trend in risk starting from 25g/day (RR= 1.12 (1.06-1.18)  |
| Child abuse (E967).                           | NA                    | NA  |

### 3.1.1 Alcohol and all-cause mortality

All of these studies consider the likely effect of alcohol on all-cause mortality. A narrative synthesis is preferred here because studies use different consumption metrics over different time periods (e.g. daily, weekly, average drinking). This review includes systematic reviews and individual studies conducted in a UK setting.

#### Details of studies

Five studies met the inclusion criteria. All studies were published in English between 2002 and 2006. Two of these studies were specifically conducted using data from England and Wales (White et al, 2002; White et al, 2004).

#### Outcomes

All studies measured all-cause mortality.

#### Results

Recent reviews tend to focus not on the effects of alcohol consumption *per se* but rather on the differential effects of different patterns and volumes of consumption. All studies identified a beneficial effect from low levels of alcohol drinking which was reversed to a detrimental effect at higher levels of consumption. The threshold for this increased level of risk varies according to the specific research question and the choice of measurement units.

White and colleagues (2002) examined the relationship between alcohol consumption and risk of death using published systematic reviews and population data from England and Wales. They identified a direct dose-response relation between alcohol consumption and risk of death in women aged 16-54 and in men aged 16-34. Risk increases by 5% above the minimum at 8 units per week in women aged 16-24 and 5 units a week in men aged 16-24, increasing to 20 and 34 units a week in women aged over 65 and men aged over 65 respectively. They thus concluded that substantially increased risks of all-cause mortality can occur even in people drinking lower than recommended limits, and especially among younger people.

A subsequent study by the same authors (White et al, 2004) examined mortality attributable to different levels in addition to all-cause mortality for England and Wales in 1997. In particular the authors examined any drinking; drinking above the nadir (level of alcohol consumption carrying the lowest risk); and drinking more than the British Royal Colleges' recommended limits of 21 units/week in men and 14 units/week in women. They found that deaths from ischaemic heart disease prevented by alcohol consumption (11 276 in men, 4050 in women) roughly balanced other deaths attributable to alcohol consumption (9246 in men, 4216 in women). Data on the implications of different drinking levels is presented below. The authors concluded that drinking above recommended limits remains responsible for many deaths and a large loss of person-years of life.

**Table 16 Percentages of deaths at different drinking levels (England & Wales)**

| <i>Level</i>                         | <i>Males – Percentages of Deaths (95% CI)</i> | <i>Females – Percentages of Deaths (95% CI)</i> |
|--------------------------------------|---|---|
| Any drinking                         | 0.8% (0.2%-1.3%)                              | 0.1% (-0.3%-0.4%).                              |
| Drinking more than recommended limit | 2.1% (1.9-2.3%)                               | 0.8% (0.6-1.0%)                                 |
| Drinking above nadir <sup>a</sup>    | 2.8%  | 1.2%  |

<sup>a</sup>Level of alcohol carrying the lowest risk

| Drinking above nadir <sup>a</sup>    | 12.6%  | 6.0%   |

<sup>a</sup>Level of alcohol carrying the lowest risk

Castelnuovo et al (2006) identified thirty-four studies that they synthesised in a meta-analysis that included 1,015,835 subjects and 94,533 deaths. They report the widely-reported J-shaped relationship

between alcohol and total mortality. Whereas consumption of up to 4 drinks per day in men and 2 drinks per day in women was inversely associated with total mortality higher doses of alcohol were associated with increased mortality. Importantly they discovered that the protective effect of low levels of alcohol disappeared at a lower level in women than in men. It should be recognised, however, that reduction of all-cause mortality is a crude measure of health benefit and fails to capture the wide range of health outcomes that need to be considered by policy-makers.

Only three of the cohort studies used by Castelnuovo and colleagues (2006) were derived from observations made in England (Britton and Marmot, 2004; Doll et al, 2005; and Wannamethee and Shaper, 1999). The youngest age included in these studies was 35 (Britton and Marmot, 2004) and this same study was the only one to include both male and female subjects. It is therefore worth recording that it is problematic to link these data to several of the priority groups that are the focus of the current reviews. Furthermore, this meta-analysis grouped all European studies together in its sub-analysis thereby potentially obscuring the beneficial effects of the Mediterranean diet against the observations of these three studies.

Burger et al (2004) attempted to weigh the risks of moderate alcohol consumption against its benefits and included all-cause mortality amongst outcomes examined. They evaluated over 350 studies although much smaller subsets of studies were used to examine each individual outcome. Twenty-seven prospective studies were used to examine all-cause mortality in adults of 40 or more years of age. They identified a maximum risk reduction in men at 19g/day and in women at 10g/day (roughly equivalent to 2.2 and 1.2 UK alcohol unit, respectively).

### **Limitations**

A number of authors (San Jose 2003, Fillmore et al, 2006, Harriss et al, 2007) highlight a consistent methodological problem across studies in relation to the composition of groups identified as “abstainers”. Those drinking are more likely to abstain from drinking in the presence of disease. These “sick-quitters” are typically included with those who never drank and artificially inflate the health risk among abstainers by bringing their already elevated health risk with them when moving into the abstainers category. The abstainer category is then typically used as the reference group with which those with moderate consumption are compared. Fillmore et al (2006)’s meta-analysis compares the effect sizes of studies that do and do not include former and occasional drinkers in the abstention category. In the “error-free” studies, the protective effect of moderate consumption (i.e. no J-shaped curve) is not observed. See also the “Limitations” paragraph in the section on coronary heart disease.

Increasingly, too, it is drinking patterns, not merely average alcohol intake, that are found to determine alcohol mortality. Although there are several constituent UK studies none cover the particular policy priority groups targeted by this review.

**Evidence statement 13: There is consistent evidence to suggest that alcohol consumption is associated with substantially increased risks of all-cause mortality even in people drinking lower than recommended limits, and especially among younger people. . High levels of alcohol consumption have detrimental effects. The evidence is more equivocal, however, where it relates to establishing cut-off points for lower risk versus harmful levels of consumption. There is an ongoing controversy as to whether or not there are beneficial (cardio-protective) effects at low levels of alcohol consumption.**

**Table 189 Relationship between alcohol consumption and all-cause mortality**

| <b>Condition</b>    | <b>Meta-analysis</b>                            | <b>Findings</b>  |
|---------------------|---|--|
| All-cause mortality | White et al (2002)                              | Direct dose-response relation between alcohol consumption and risk of death in women aged 16-54 and in men aged 16-34. Risk increases by 5% above minimum at 8 units in women aged 16-24 and 5 units a week in men aged 16-24, increasing to 20 and 34 units a week in women and men aged over 65 respectively. Substantially increased risks of all-cause mortality can occur even in people drinking lower than recommended limits, especially younger people. |
|                     | White et al (2004)                              | Deaths from ischaemic heart disease prevented by alcohol consumption (11 276 in men, 4050 in women) roughly balanced other deaths attributable to alcohol consumption (9246 in men, 4216 in women).<br>Drinking above recommended limits is responsible for many deaths and a large loss of person-years of life.  |
|                     | Burger et al (2004)<br>Castelnuovo et al (2006) | Maximum risk reduction in men at 19g/day and in women at 10g/day.<br>Confirms widely-reported J-shaped relationship between alcohol and total mortality.<br>Consumption of up to 4 drinks per day in men and 2 drinks per day in women was inversely associated with total mortality. Higher doses of alcohol associated with increased mortality. Protective effect of low levels of alcohol disappeared at lower level in women than in men.                   |
|                     | Filimore et al (2006)                           | Find that protective effect of alcohol at moderate consumption levels compared to abstainers is dependent on how the "abstainers category" is defined. Protective effects were not found when moderate drinkers were compared to "true abstainers" rather than groups of abstainers which included former drinkers.  |

### 3.1.2 Coronary heart disease

Coronary heart disease (CHD) is a major cause of disease burden and of mortality around the world. It has therefore figured prominently in discussions of alcohol-related harm. This situation is complicated by the complex relationship between alcohol and coronary heart disease.

Rehm et al (2003) identified seven meta-analyses that examined the association between alcohol consumption and risk of coronary heart disease. He concluded that patterns of drinking must be included in the analysis. He was unable to perform his own meta-analysis because of the heterogeneity of reviews. Light to moderate consumption has been consistently shown to be linked to favourable CHD outcomes. In contrast, episodes of heavy drinking, even where linked to average light or moderate consumption, have been shown to relate to increased CHD risk (Rehm et al, 2003). There is an increased understanding of how this beneficial effect of light to moderate drinking may operate. Explanations include favourable lipid profiles (especially increased high-density lipoproteins and favourable coagulation profiles (Rimm et al, 1999). Other mechanisms have been suggested but none commands such prominence as the two identified above.

#### Details of studies

Our review identified three further meta-analyses of coronary heart disease, performed by Corrao et al (2004), Burger et al (2004) and Iestra et al (2005). Corrao et al (2004) selected 28 cohort studies from an initial pool of 51 studies. All included studies were published in English between 1966 and 1998. Burger et al (2004) found 18 studies that met quality criteria and used them to evaluate the risk association of alcohol consumption for CHD.

#### Outcomes

Studies typically measured the relative risk of coronary heart disease.

#### Results

Corrao et al (2004) found a statistically significant protective effect at doses of 25g/day (0.81 (95% CI 0.79-0.83)) and 50g/day (0.87 (95% CI 0.84-0.90)). However at a dose of 100g/day the effect became detrimental (1.13 (95% CI 1.06-1.21)).

Burger et al (2004), examining 18 studies that evaluate the association between consumption of alcohol and risk of CHD, present a uniform finding that alcohol consumption of less than 14g/day is associated with beneficial effects on CHD when compared with non-drinking. Risk reduction was most pronounced for women drinking 14–29 g alcohol/day and for men drinking 29–43 g alcohol/day, with a generally smaller benefit or no benefit at all for those drinking more. The most obvious beneficial health effect of alcohol consumption was observed for persons aged 50 years and older.

Whereas most of these studies examine the evidence for the general population, Iestra et al (2005) has looked at the effects of alcohol on those already diagnosed as having coronary artery disease (CAD). CAD patients differ from the general population primarily being older and undergoing treatment with preventive drugs. This review sought to identify prospective cohort studies and randomized controlled trials of patients with established CAD that report all-cause mortality and have at least 6 months follow-up. Relative risks (RR) for moderate alcohol use (RR, 0.80; 95% CI, 0.78 to 0.83) were identified.

#### Limitations

Systematic error in the definition of abstainers in previous studies (typically combining non-drinkers, former drinkers and light occasional drinkers) might explain much of the cardio-protective effect (Fillmore et al, 2006; Harriss et al 2007). Beyond the question of whether there is a relationship, there is the question of the size of the effect, which is much overestimated in the calculations which have been standard. When Swedish researchers used standard calculations in a cost-of-illness study, they found that 42% of the women being "saved" were aged 80 and over (Johansson et al 2006) The result arises because most CHD deaths are among the very old, while prospective studies on which Relative Risks typically follow people in their 40s or 50s. Jackson et al (2005) are also sceptical about the size of the effect, particularly at low drinking levels. A newly published meta-analysis (Djoussé and Gaziano 2008) identified as the final report was being written (and hence not appraised) finds that drinking patterns and genetic factors may explain some of the variation around this topic.

### Summary

A WHO Expert Committee on Problems Related to Alcohol Consumption met (2006) to review public health problems attributable to alcohol consumption. They concluded that “even in societies where heart disease is a very important cause of death, the overall number of lost years of life attributable to drinking outweighs the saved years attributable to protective effects”.

**Evidence statement 14: There is moderate, but methodologically disputed, evidence to suggest that light alcohol consumption is associated with a decreased level of risk from coronary heart disease. High levels of alcohol consumption (defined here as 100g/day) have detrimental effects (RR = 1.13 (95% CI 1.06-1.21)).**

**Table 19 Relationship between alcohol consumption and coronary risk factors**

|   |                                    |                |  |                     |  |

### 3.1.3 Stroke

Rehm (2003) identified seven meta-analyses that examined the association between alcohol consumption and risk of stroke. He identified important differences in risk in terms of type of stroke and average volume of consumption. He was unable to perform his own meta-analysis because of the heterogeneity of reviews.

#### Details of studies

Our review identified one further meta-analysis of stroke, performed by Reynolds et al (2003). This examined a total of 35 observational studies (19 cohort and 16 case-control studies). All included studies were published in English between 1966 and April 2002. Included populations were categorised according to average alcohol intake of less than 12g/day; 12-24g/day; 24-60g/day and over 60g/day.

#### Outcomes

Included studies measured occurrence of stroke only. The review did not report mortality.

#### Results

Results indicate that heavy alcohol consumption (more than 60g alcohol/day) increases the relative risk of stroke. Light or moderate alcohol consumption (less than 12g per day) may be protective against total and ischaemic stroke.

### **Limitations**

The majority of included studies were conducted in the U.S or mainland Europe. Only studies by Shaper et al (1991); Palmer et al (1995); Hart et al (1999) from 19 cohort studies and studies by Gill et al (1986); Gill et al (1988); Gill et al (1991); Ben-Shlomo et al (1992); Shinton et al (1993) from 16 case-control studies were conducted in the United Kingdom.

### **Summary**

Meta-analysis revealed a J-shaped relationship between alcohol consumption and total and ischaemic stroke and a linear relationship between alcohol consumption and haemorrhagic stroke.

**Evidence statement 15: There is strong evidence that heavy alcohol consumption increases the risk of stroke. Light or moderate consumption may be protective against total and ischaemic stroke, although the evidence on this is not as clear and it is important to acknowledge that this effect is not consistent for all types of stroke.**

### **3.1.4 Neoplastic Diseases**

All of these studies consider the relationship between alcohol consumption and various cancers. The review of reviews by Rehm (2003) found consistent evidence for a causal relationship for lip and oropharyngeal cancer; oesophageal cancer; female breast cancer; liver cancer and laryngeal cancer. Rehm (2003) found inadequate evidence for a causal relationship for stomach cancer, colon cancer, rectal cancer, lung cancer, ovarian cancer and prostate cancer

#### **Details of studies**

A total of 8 systematic reviews met the inclusion criteria. (Table 22) All reviews were published in English, between 2001-2007. The study by Corrao et al (2004) covered most of the neoplastic conditions. Moskal et al (2007) covered more than one condition. The largest number of reviews were located for colon cancer and rectal cancer (3 studies each). Stomach cancer was not included in any identified reviews.

#### **Outcomes**

The majority of studies examined mortality rather than morbidity. Although this has the advantage of being a definitive and unequivocal outcome this may result in an underestimation of the effects of alcohol in terms of burden of illness. There is a consistent pattern across many studies of moderate drinking being of marginal risk but higher levels resulting in heavily increased risk.

#### **Results**

There is therefore consistent evidence for a causal relationship for lip and oropharyngeal cancer; oesophageal cancer; female breast cancer; liver cancer and laryngeal cancer. Considerable uncertainty exists, however, in specific relation to the association of moderate alcohol consumption and breast cancer. Alcohol intake of at least 30g-40g/day increased the risk of breast cancer but the extent of this risk was found to be low and no risk elevation was found below 20g/day (Burger et al, 2004).

No additional review was found for stomach cancer. There is therefore still inadequate evidence on whether alcohol causes stomach cancer.

The three reviews looking at colon cancer support a statistically significant association with alcohol consumption at levels greater than 45g/day (Moskal et al, 2007). Similarly, for rectal cancer there was a statistically significant association with alcohol consumption, this time at the lower level of 30g/day. Evidence from one review, by Freudenheim et al (2005), confirms the difficulties of establishing a causal relation with lung cancer initially reported in Rehm's review. The authors report a slight trend to greater risk for 30g/day but suggest that residual confounding by smoking may explain some of this effect. Genkinger et al (2006) similarly confirm that studies examining ovarian cancer have failed to establish a causal link to alcohol and Dagnelie et al (2004) find likewise for prostate cancer.

#### **Summary**

All the reviews identified as published since Rehm's review therefore confirm the state of evidence for all neoplastic conditions as an accurate synopsis for the present time. Not only do none of the reviews contradict Rehm's overall verdict on each condition but the same difficulties in interpretation or lack of availability of evidence (e.g. for stomach cancer) continue to persist.

**Evidence statement 16: There is strong evidence for statistically significant associations with a wide range of cancers including some of the most common cancers in the UK. However the evidence is not consistent across all neoplastic conditions. Further research is required for stomach and lung cancer in particular.**

**Table 21 Chronic alcohol-related health effects (neoplastic conditions) identified by various meta-analyses**

| Disease                      | ICD-9                              | Deaths England and Wales (1997) (White et al, 2004)  | Effect (According to Rehm et al (2003)) | Recent Meta-analyses   | Findings   |

### 3.1.5 Traffic injuries and deaths

Two meta-analyses were identified examining the effects of alcohol consumption on the incidence of traffic injuries and mortality.

**Evidence statement 17: There is a significant and consistent effect between alcohol consumption and serious injury and for heavy drinking and road accidents. Heavy drinking levels of 5 drinks or more were found to be positively predictive of injury.**

**Table 20 Evidence for an association between alcohol consumption and risk of traffic accidents**

| <b>Condition</b> | <b>Meta-analysis</b>    | <b>Findings</b>   |
|------------------|-------------------------|---|
|                  | Cherpitel et al (2003a) | Significant, but not homogenous, effect size for consuming 5+ drinks on an occasion at least monthly with odds ratios (ORs) of 4.16 for positive blood alcohol concentration (BAC) and 3.92 for self-report. Frequency of drinking among non-heavy drinkers had largest effect size (5.93 for BAC and 4.93 for self-report). Heavy drinking, controlling for frequency, was also significant (ORs of 2.08 for BAC and 1.86 for self-report), but effect size was homogeneous only for self-report.  |
|                  | Cherpitel et al (2003b) | Pooled odds ratios for blood alcohol concentration at time of emergency room visit and amount of alcohol consumed in 6 hr before injury were positively predictive (1.19 and 1.80, respectively) and heterogeneous across studies. Effect size changed little when age and gender were controlled. For drinkers reporting five or more drinks on an occasion during the last year, amount consumed was positively predictive of reporting a causal association of drinking and injury. Effect size of feeling drunk at time of injury, controlling for amount of alcohol consumed, was positively predictive (2.04) but heterogeneous across studies. |

### 3.1.5 Suicides

These systematic reviews consider the relationship between alcohol consumption, both in terms of chronic alcohol dependence or acute episodes of heavy drinking, and suicide (E950-959) or attempted suicide. No further meta-analysis or synthesis has been attempted.

#### Details of studies

3 reviews met the inclusion criteria these were published in English, between 2004 and 2007. They therefore update the review by Rehm. Wilcox et al (2004) specifically examined the effect of heavy drinking on suicide.

**Table 23 Systematic reviews associating alcohol consumption with suicide (3 studies)**

| <b>Condition</b>   | <b>Meta-analysis</b>         | <b>Findings</b>  |
|--------------------|------------------------------|--|
| Suicide (E950-959) | Cargiulo (2007)              | Alcohol dependence associated with increased risks of suicide (OR 2.13 95% CI 1.18-3.85) and suicide attempts (OR 2.50 95% CI 1.38-4.52) |
|                    | Norström and Ramstedt (2005) | (Data pending)   |
|                    | Wilcox et al (2004)          | Overall SMR for heavy drinking was 351 (95% CI 251-478) while it was 39 (95% CI 5-140) for males   |

### Outcomes

The three systematic reviews measured mortality associated outcomes presented either as odds ratios or as a standardised mortality ratio. Attempted suicide was also considered as an outcome (Cargiulo, 2007).

### Results

All three reviews presented an association between alcohol consumption and either suicide or attempted suicide.

**Evidence statement 18: There is moderate and consistent evidence to suggest that alcohol dependence is associated with increased risks of suicide (OR 2.13 95% CI 1.18-3.85) and suicide attempts (OR 2.50 95% CI 1.38-4.52). There are methodological difficulties in making an attribution of suicide to the harmful effects of alcohol.**

### 3.1.6 Alcohol and sexually transmitted diseases

Alcohol consumption does not itself cause sexually transmitted diseases. However, it can directly affect risk either by increasing the risk that one is exposed to an STD through risky sexual behaviour and alcohol may also compromise the capability of the immune system to fight infections.

#### Details of studies

Cook & Clark (2005) conducted a systematic review of the relationship between alcohol consumption and sexually transmitted diseases (STD). They identified 42 eligible studies, of which only 11 included a measure of alcohol consumption that could be used to identify hazardous drinking.

#### Results

Eight of the 11 identified studies found an increased risk of STD, and the other three found no significant association. Results from studies with general measures of alcohol consumption were similar, with most finding a significant association with at least one STD.

#### Limitations

Of the three studies failing to find an effect, one had a very small sample size, another used a very insensitive measure of STD, and the third just missed achieving statistical significance. The 42 articles included over 30 different types of alcohol measurement descriptions, making it difficult to reach clear conclusions about which particular pattern of alcohol consumption is associated with the greatest risk.

**Evidence statement 19: There is moderate evidence (from eight out of eleven studies included in a systematic review) to suggest that alcohol consumption is associated with increased incidence of sexually transmitted diseases. Because there are other possible explanations for risk behaviours there are significant difficulties in establishing a consistent mechanism for direct causal effects. However, this finding is supported by studies directly associating taxation or pricing changes for alcohol with changes in rates of sexually transmitted diseases including gonorrhoea.**

**Table 21 Alcohol consumption and risk of sexually transmitted diseases**

| <b>Condition</b>              | <b>Meta-analysis</b> | <b>Findings</b>   |
|-------------------------------|----------------------|---|
| Sexually transmitted diseases | Cook & Clark (2005)  | Problem drinking is clearly associated with an increased risk of STDs across a wide variety of populations. |

### 3.2 Alcohol consumption and social harm

Gmel and Rehm (2003) provide a definitive overview of social consequences of alcohol abuse. They begin by linking social consequences with the following elements of the DSM-IV for the definition of alcohol abuse:

1. Failure to fulfill major role obligations at work, school, or home (e.g., repeated absences or poor work performance, neglect of children or household)
2. Continued drinking even in situations where it is physically hazardous (e.g., driving an automobile or operating machinery)
3. Recurrent alcohol-related legal problems (e.g., arrests for disorderly conduct while drinking)
4. Continued drinking despite persistent or recurrent social or interpersonal problems it may cause (e.g., arguments with spouse, physical fights).

In accordance with this many commentators have looked at consequences relating to each category such as workplace absenteeism, unintentional injuries, and violence.

#### 3.2.1 Violence

Attribution of violence or injury to alcohol consumption is important in assessing the burden of alcohol on society. Attribution has been assessed in several ways:

- Using *aggregate level data* collected on exposure rates to the risk factor (alcohol) and the relative risk of injury due to the use of alcohol in the event.
- Using *individual level assessments* of whether or not the injury would have occurred if the respondent had not been drinking alcohol (assessed across a range of consumption levels).

Both methods have their limitations – the former in being unable to establish a causal link between exposure and outcome and the latter in relying on individual perceptions of attribution (which may lead to under- or over-reporting). Alcohol-related costs of crime and disorder are put at £7.3 billion, and some 47% of victims of violence say that they believed their assailant to be under the influence of alcohol at the time of their attack. Health costs are estimated at an additional £1.7 billion a year (Academy of Health Sciences 2004). All of the included studies consider violence whether directed at strangers or at members of the more intimate circle of friends or family. Male alcohol consumption is an accepted risk factor for intimate partner violence.

#### Details of studies

Gil-Gonzalez and colleagues (2006) conducted a systematic review and meta-analysis of quantitative studies conducted between 1966–2004. Eight databases from Social and Behavioural Sciences, Clinical Medicine, and Life Sciences were reviewed. 22 studies fulfilled the inclusion criteria for the systematic review: 14 were cross-sectional studies, 6 case–series and 2 case–control studies. Ten studies analysed the relationship between alcohol and violence as their primary hypothesis.

Corrao et al (2004) included violence as an outcome of interest in their review of 15 health conditions attributable to alcohol. Grouping violence with injuries (there is no separate analysis) they observed a consistent and significant effect of alcohol at various levels of intake (25g/day 1.12 (1.06 –1.18); 50g/day 1.26 (1.13– 1.40) and 100g/day 1.58 (1.27 –1.95).

English et al (1995), Schultz et al (1991) and Single et al (1998) have used *meta-analysis* to attempt to establish a causal link between alcohol use, crime and violence (Rehm et al 2006).

**Table 22 Percentage of violent events attributed to alcohol use**

| Type of violence              | English <i>et al</i> (1995) | Schultz <i>et al.</i> (1991) | Single <i>et al</i> (1998) |
|-------------------------------|-----------------------------|------------------------------|----------------------------|
| Homicide or purposeful injury | 47                          | 46                           | 27                         |
| Suicide                       | 41 (m), 16 (f)              | 28                           | 27 (m), 17 (f)             |

### Results

For 11 papers included in the meta-analysis by Gil-Gonzalez et al (2006) the overall pooled odds ratio was 4.57 (95% CI 3.30–6.35), but a high degree of heterogeneity was observed. The magnitude of the effect was inversely associated with the year of publication. The biggest odds ratios were obtained in studies with small sample sizes.

### Limitations

Only two studies examined by Gil-Gonzalez et al (2006) used a direct measure of alcohol consumption.

Evidence for a relationship between alcohol consumption and intimate partner violence is of low quality and may be subject to publication bias. Gil-Gonzalez and colleagues (2006) conclude that currently there is not enough empirical evidence to support preventive policies based on male alcohol consumption as a risk factor in the particular case of intimate partner violence.

**Evidence statement 20: There is a consistent and statistically significant effect of alcohol on violence and injury at even quite low levels (25g/day) of consumption. Further research of higher quality using more rigorous designs is required to establish a robust causal explanation.**

### 3.2.2 Divorce and marital problems

In a meta analysis, Marshal (2003) reports strong associations between alcohol consumption and marital dissatisfaction, negative interactions, and violence, and some empirical evidence of positive effects of light alcohol consumption on marital functioning. 60 studies were included in his meta-analysis.

Alcohol consumption is described in terms of the quantity and frequency of alcohol consumed in a given period i.e. how often an individual drinks (frequency) or how much an individual drinks in one sitting (quantity). Quantity–frequency indices are often employed by studies in this review and are used to calculate average daily or weekly estimates of a drinkers' volume of alcohol consumption.

### Limitations

Despite strong evidence in support of a harmful effect of heavy alcohol use many of these studies are characterized by methodological limitations that threaten internal and external validity of their results. These limitations include small sample sizes, poor measurement quality and over-reliance on treatment samples.

### Summary

There is considerable evidence supporting the conclusion that heavy and problematic alcohol use is associated with lower levels of marital satisfaction, higher levels of maladaptive marital interaction patterns, and higher levels of marital violence.

**Evidence statement 21: There is a strong and consistent association between alcohol consumption and marital dissatisfaction, a risk factor for subsequent divorce. Further research is required to establish the direction of cause and effect.**

### 3.2.3 Crime other than violence

Alcohol's close association with violent events (interpersonal and personal) has been documented (e.g. from prison studies, studies of sexual violence). This association stops short of causality. Collins (1982) explored the relationship between alcohol consumption and criminal behaviour. He concluded that there was sufficient evidence to justify the inference that alcohol is sometimes causally implicated in the occurrence of serious crime. He did point to the need for further empirical research and despite the ensuing years there is still a shortage of such evidence. This review did not identify any recent systematic reviews or meta-analyses of the effect of alcohol consumption on criminal behaviour. Currently the best evidence in terms of both rigour and relevance comes from the Home Office study by Richardson & Budd (2003). These investigators used multivariate analysis to confirm that, even when other factors were taken into account, frequency of drunkenness was still an important indicator of offending and disorderly behaviour. This was particularly apparent for violent crime. They calculated that 18-24-year-olds who got very drunk at least once a week had five and a half times the odds of admitting to a violence offence than those who got drunk less than once a month. The 2003 *Offending, Crime and Justice Survey* (Mathews & Richardson, 2005) found that binge drinkers were more likely to offend than others, and accounted for a disproportionate amount of the total number of crimes. In fact binge drinkers comprised 6% of the adult sample, but they accounted for 30% of all crimes reported, and 24% of all violent incidents,

### Employment

Employment is another domain that is significantly impacted by alcohol consumption. Again the review was unable to identify a recent systematic review or meta-analysis covering this topic. There have been some attempts to conduct econometric studies of this domain. This is challenging given the wide variety of outcomes that might be selected for measurement and subsequent analysis. A key study, already included in Review 1 of this report is USA-based modelling work by Dave and Kaestner (2002) who examined the effect of alcohol taxes on employment, weekly work hours, and wages. They used the resulting analysis to explore the structural effects of alcohol use on labour market outcomes. They concluded that there is a weak and indeterminate relationship between alcohol taxes and labour market outcomes but acknowledged that, although this implies that alcohol use does not adversely affect labour market outcomes, this was inconsistent with findings from previous studies.

**Evidence statement 22: No recent systematic reviews or meta-analyses were identified that examined the effects of alcohol on crime other than violence or on employment-related outcomes such as unemployment or absenteeism. There is sufficient non-review evidence to suggest that a significant proportion of criminal behaviour can be associated with alcohol misuse. However it is methodologically difficult to ascertain the alcohol attributable fraction for this association.**

### 3.2.5 Alcohol and social problems: overall findings

Alcohol misuse can harm people other than the drinker, and can have negative consequences for society as a whole (Gmel & Rehm, 2003). It is believed to play a role in decreased worker productivity, increased unintentional injuries, aggression and violence against others, and child and spouse abuse. The evidence base does support an association between alcohol consumption and many of these social harms, but is not able to support a causal effect of such outcomes. Much of the research in this area has been criticised on the basis of methodological flaws and a requirement for better design and statistical methodology has been identified (Gmel & Rehm, 2003).

### 3.3 Conclusions

The above review builds upon earlier work by Rehm (2003) and by Gmel and Rehm (2003), together with the influential *Alcohol in Europe* report (Anderson, & Baumberg, 2006), in identifying multiple associations and several causal links between alcohol consumption and the harmful effects on health and society (including crime and violence). While the evidence is not conclusive for all conditions it is of sufficient quantity and quality to support an increased level of intervention for both economic and public health-related reasons. Where the evidence base is less conclusive is in relation to the levels at which harm may be attributed.

Nevertheless the seminal study by Corrao et al (2004) demonstrates across 15 conditions that transition from a 25g/day threshold to other levels of consumption is associated with a significant increase in risk for most, but not all, of these conditions.
