What evidence is there on the effectiveness of different models of delivering urgent care?
A rapid review.

This web report has been created once the normal NIHR Journals Library peer and editorial review processes are complete. The report has undergone full peer and editorial review as documented at NIHR Journals Library website and may undergo rewrite during the publication process. The order of authors was correct at editorial sign-off stage.

A final version (which has undergone a rigorous copy-edit and proofreading) will publish in a forthcoming issue of the Health Services and Delivery Research journal.

Any queries about this web report should be addressed to the NIHR Journals Library Editorial Office NIHedit@soton.ac.uk.

The research reported in this web report was commissioned and funded by the HS&DR programme as part of a series of evidence syntheses under project number 13/05/12. For more information visit http://www.nets.nihr.ac.uk/projects/hsdr/130512

The authors have been wholly responsible for all data collection, analysis and interpretation, and for writing up their work. The HS&DR editors have tried to ensure the accuracy of the authors’ work and would like to thank the reviewers for their constructive comments however; they do not accept liability for damages or losses arising from material published in this web report.

This web report presents independent research funded by the National Institute for Health Research (NIHR). The views and opinions expressed by authors in this publication are those of the authors and do not necessarily reflect those of the NHS, the NIHR, NETSCC, the HS&DR programme or the Department of Health. If there are verbatim quotations included in this publication the views and opinions expressed by the interviewees are those of the interviewees and do not necessarily reflect those of the authors, those of the NHS, the NIHR, NETSCC, the HS&DR programme or the Department of Health.
Abstract

Background
In 2013 NHS England set out their strategy for development of an emergency and urgent care system that is more responsive to patients’ needs, improves outcomes and delivers clinically excellent and safe care. Knowledge about the current evidence base on models for provision of safe and effective urgent care, and the gaps in evidence which need to be addressed can support this process.

Objective
The purpose of the evidence synthesis is to assess the nature and quality of the existing evidence base on delivery of emergency and urgent care services and identify gaps that require further primary research or evidence synthesis.

Methods
We have conducted a rapid framework-based evidence synthesis approach. Five separate reviews were conducted linked to themes in the NHS England review. A general and five theme specific database searches were conducted for the years 1995-2014. Relevant systematic reviews and additional primary research papers were included with narrative assessment of evidence quality was conducted for each review.

Results
The review was completed in six months. In total 45 systematic reviews and 102 primary research studies have been included across all 5 reviews. The key findings for each reviews were 1) Demand - there is little empirical evidence to explain increases in demand for urgent care, 2) Telephone triage - Overall, these services provide appropriate and safe decision making with high patient satisfaction but required clinical skill mix and effectiveness in a system is unclear, 3) extended paramedic roles have been implemented in various health settings and appear to be successful at reducing transports to hospital, making safe decisions about the need for transport and delivering acceptable, cost-effective care out of hospital. 4) ED – The evidence on co-location of GP services with ED indicates there is potential to improve care. The attempt to summarise the evidence about wider ED operations proved to
be too complex and further focused reviews are needed. 5) There is no empirical evidence to support the design and development of urgent care networks.

Limitations
Although there is a large body of evidence on relevant interventions much of it is weak with only very small numbers of randomised controlled trials identified. Evidence is dominated by single site studies many of which were uncontrolled.

Conclusions

The evidence gaps of most relevance to the delivery of services are 1) more detailed understanding and mapping of the characteristics of demand to inform service planning, 2) assessment of the current state of urgent care network development and evaluation of effectiveness of different models, and 3) Expanding the current evidence base on existing interventions that are viewed as central to delivery of the NHS England plan by assessing the implications of increasing interventions at scale and measuring costs and system impact. It would be prudent to develop a national picture of existing pilot projects or interventions in development to support decisions about research commissioning.

Scientific Summary

Background

Demand for urgent care (including emergency care) has increased year on year over the last 40 years. The reasons for this are only partly understood but comprise a complex mix of changing demographic, health and social factors. Over the last 15 years there have been a number of reviews of urgent care, policy recommendations for service changes and service level innovations all of which were aimed at improving access to and delivery of urgent care. Despite this the emergency and urgent care system remains under greater pressure than ever. It is increasingly recognised that provision of urgent care is a complex system of interrelated services and that this whole system approach will be key to improvement and development in the future. In 2013 NHS England set out their strategy for development of a system that is more responsive to patients’ needs, improves outcomes and delivers clinically excellent and safe care. Knowledge about the current evidence base on models for provision of safe and effective urgent care, and the gaps in evidence which need to be addressed can support this process.

Objectives

1) To examine the evidence on delivery of care relating to 5 themes:
   - Understanding demand for emergency and urgent care
   - Access and direction to the right service - Telephone triage and advice services
   - Managing urgent care outside hospital - Patient management by paramedics in the community
   - Delivery of Emergency Department services
   - Emergency and urgent care networks
2) What is the quality of that evidence?
3) What are the main/significant evidence gaps?
Methods

We have utilised a rapid framework-based evidence synthesis approach to ensure the efficient identification and synthesis of the most relevant evidence. A separate review has been conducted for each of the 5 themes. A range of search methods were used. Firstly a broad general search on Medline. This was then supplemented with targeted database searches for each of the five themes. Searches were conducted for the years 1995-2014. To increase efficiency, where appropriate we have utilised existing search strategies from related research we have conducted within ScHARR or from existing related systematic reviews. Additional references were identified by scrutinising reference lists of included systematic reviews, utilising our own extensive archive of related research and internal and external topic experts. Searches were sifted by a single reviewer and a 10% random sample checked by a second reviewer. Only empirical evidence was included. Data extraction from individual studies was only carried out for papers that met the inclusion criteria and had not been included in a systematic review. Data was extracted directly into summary tables. We did not conduct formal quality assessment but provided a narrative summary of study quality based on the limitations reported by study authors. We have summarised the evidence for each theme and identified common issues that overlap between themes.

Results

We have conducted five separate rapid evidence reviews on themes related to the delivery of emergency and urgent care in the NHS. These themes were trends in and characteristics of demand; telephone triage and advice; management of patients in the community by ambulance clinicians; models of service delivery in the Emergency Department and Emergency and urgent care networks.

Demand for emergency and urgent care

Four systematic reviews and 39 primary studies were included. There is remarkably little empirical evidence that can fully explain the increases in demand for urgent care. The evidence key gaps and challenges identified from the existing evidence relate to a need to examine demand from a whole system perspective and gain better understanding of the
relative proportions of demand for different parts of the system and the characteristics of patients within each sector. This could be addressed by developing research studies that build on the existing knowledge about factors which may be influencing demand and the contribution each one makes, and map these in to a coherent system model. This would then support the development of service design and planning to meet current and future needs of local populations.

**Telephone triage and advice**

10 systematic reviews and 44 primary studies were included. There is an existing, substantial evidence base about the operational and clinical effectiveness of telephone based triage and advice services for management of requests for urgent healthcare. Overall, these services provide, appropriate and safe decision making, patient satisfaction is generally high as is the likelihood that patients will accept advice although this varies depending on the clinician providing it. There is little evidence though on efficiency of these services from a whole system perspective. Evidence gaps and aspects of service delivery that warrant further study are centred around the need for 1) further assessment of the whole system impact of telephone access services for emergency and urgent care, including the associated costs, to establish how it contributes improving system efficiency 2) more focused research on the broad area of the optimum requirements for different skill levels needed in the NHS 111 service and 3) more detailed evaluation of the accuracy and appropriateness of call assessment decisions would help answer some of the questions about the appropriateness of referrals made by the NHS 111 service.

**Management of patients with urgent care needs by the ambulance service in community settings**

Seven systematic reviews and 12 primary studies were included. Extended paramedic roles have been implemented in various health systems and settings and appear to be successful at reducing transports to hospital, making safe decisions about the need for transport, delivering acceptable care out of hospital and are potentially cost-effective. The key evidence gaps and areas for further research include 1) further work on ways to support paramedic decision-making and development of integrated care pathways for a range of conditions that mediate safe management in the community setting, 2) more detailed study on the necessary skill-mix...
of paramedics and paramedics with advanced and specialist skills needed to provide a safe and high quality community based service for patients, 3) more accurate estimations of the likely proportion of patients who could be safely managed outside hospital to support ambulance resource and paramedic workforce planning.

Models of service delivery in the Emergency Department

Attempting to assess the evidence on different models of delivering ED services was challenging. We conducted 2 reviews. One updated and existing systematic review on co-location of primary care and ED identified potential for this initiative. Two systematic reviews and 7 primary studies were included in this review. We have only been able to conduct a “review of reviews” (22 systematic reviews) about the wider ED service and given the complexity of the subject area we have been unable to identify clear evidence gaps. The review highlighted some areas worth further consideration, 1) additional focused reviews utilising the existing search library with, where necessary targeted focused additional searches. One of these could be management of the frail elderly in ED as this is a key area for development but there is little evidence on interventions to improve care. There is scope to identify more recent primary studies from our existing search library. 2) one clear evidence gap is the lack of studies conducted at scale. The emphasis on developing co-located primary care services within ED is one area where there is an opportunity to undertake a broader study.

Emergency and Urgent Care Networks

We found no evidence on how to best organise and operate an emergency and urgent care network or any empirical evidence on effectiveness of this type of network model. Research activities which could support emergency and urgent care network development includes 1) a more detailed and targeted rapid review to further explore the related theoretical literature and identify evidence around design and strategies for successful network development, 2) some rapid scoping research to identify and map current emergency and urgent network development nationally and 3) a programme of research to evaluate emergency and urgent care network and measure effectiveness.
Some common themes were identified across subject areas. These included 1) the relationship between better understanding of the drivers of demand and the planning of health services by networks, 2) the need to develop integrated care and referral pathways to improve effectiveness for telephone services and support patient management in the community and 3) the need to measure whole service and system impact and associated costs when evaluating interventions and initiatives.

A substantial number of included studies for most themes were from the UK but none on trends in demand.

**Limitations**

This was a large scope rapid review so we have not been able to conduct a detailed analysis of the quality of the evidence base. Some key themes identified include;

- Overall, the evidence base on effectiveness of different models of care for delivering emergency and urgent care is weak with small numbers randomised controlled trial designs and reliance on uncontrolled before and after studies
- An emphasis on process measurement such as times and attendance rates rather than patient outcomes other than satisfaction
- Little attention has been paid to the costs and cost effectiveness associated with interventions

A quality assessment of the 22 systematic reviews on delivery of ED care found that, overall the quality of these reviews was good with 20/22 conducting adequate searching, 13/22 assessing risk of bias, 17/22 used appropriate methods of synthesis and in 14/22 the evidence presented was judged to support author conclusions.

The limitations to the rapid review method we have used are, 1) we have not exhaustively searched for and synthesised all the relevant literature, 2) we have drawn extensively on existing systematic reviews and 3) given the potential scope and scale there are related themes that have been excluded from this review. The most obvious gaps are separate reviews of models of urgent care within primary care and specific attention to workforce issues such as skills, education and retention. We have also not been able to include PPI input to this review but this will be of benefit when prioritising which evidence gaps should be addressed to assess importance to patients.
Conclusions

We have conducted five separate rapid evidence reviews on themes related to the delivery of emergency and urgent care in the NHS. We have found there is a paucity of evidence to explain the complex reasons that have driven the increases in demand for emergency and urgent care and to support the development of emergency and urgent care networks. There exists a considerable evidence base on the effectiveness of some interventions to improve service delivery but the evidence base is overall weak and based in small single site studies with no assessment of impact at scale or on the wider emergency and urgent care system. The evidence gaps that appear to be in most immediate need of addressing are:

- Research to characterise and map demand at a population level and link this to service need so that emergency and urgent care systems can be designed that can effectively, efficiently and safely respond to patient needs
- An assessment of the current state of play in the development of emergency and urgent care networks and longer term evaluation of the effectiveness of different network models to identify how best networks can deliver NHS England objectives
- Expanding the current evidence base on existing interventions that are viewed as central to delivery of the NHS England plan by assessing the implications of increasing interventions at scale and measuring costs and system impact.

Although not an evidence gap, a clear theme that emerged across the reviews was the need for robust, high quality and linked patient data to support these tasks.

Finally, given the large number of related programmes already at work in the NHS, it would be prudent to develop a national picture of existing pilot projects or interventions in development to support decisions about research commissioning.

Word Count - 1951
Plain English summary

The emergency and urgent care services in the NHS are under serious pressure. In response to this NHS England reviewed these services and developed a plan to transform how they work so that patients can expect to receive “the right care, in the right place, first time”. We have conducted a rapid review of the existing research evidence on five themes related to the NHS England review – factors affecting demand for care; telephone triage services (such as the NHS 111 telephone service); developing paramedics so they can treat more people at home; delivering care in A&E and developing urgent care networks to create joined up services. We have found that a substantial amount of research exists which could help support the development of services. However, research has not always been of high quality and so the benefits for patients is not always well demonstrated and the costs needed to provide services have often not been measured. We have identified three key areas that would benefit from further research, 1) a better understanding of the reasons for increasing demand and the services needed to provide patients with the right care at the right time, 2) better information on how best to develop urgent care networks so they plan services that meet the needs of local populations and 3) assess the implications for expanding existing services such as specialist paramedics.

Word Count - 228
Chapter 1 - Background

This rapid evidence synthesis has been written in response to a request by the NIHR HS&DR programme to examine the evidence around the delivery of urgent care services. The purpose of the evidence synthesis is to assess the nature and quality of the existing evidence base and identify gaps that require further primary research or evidence synthesis.

Demand for urgent care (including emergency care) has increased year on year over the last 40 years. This has been reflected in growth in Emergency Department (ED) attendances, calls to the 999 ambulance service and contacts with other urgent care services including primary care and telephone based services. The reasons for this are only partly understood but comprise a complex mix of changing demographic, health and social factors. Over the last 15 years there have been a number of reviews of urgent care, policy recommendations for service changes and service level innovations all of which were aimed at improving access to and delivery of urgent care. Figure 1 provides a summary of some of the key developments that have been widely adopted within the NHS and related policy initiatives. The timeline shows when developments were first introduced, however these have not remained static but have grown and changed over ensuing years.

Despite these initiatives the emergency and urgent care system has come under increasing strain and media attention, most commonly reported as failings in meeting government targets. Nationally, emergency departments have not met the target of treating and discharging or admitting 95% of attending patients within 4 hours for any year quarter from October 2012 to March 2015. [Link](http://www.england.nhs.uk/statistics/statistical-work-areas/ae-waiting-times-and-activity/weekly-ae-sitreps-2014-15/). Similarly there has been a reduction in the ability of ambulance services to meet the national target of responding to 75% of life-threatening calls (Red1) within 8 minutes. Performance nationally reduced from 76.2% in March 2014 to 73.4% in March 2015 [Link](http://www.england.nhs.uk/statistics/statistical-work-areas/ambulance-quality-indicators/), whilst at the same time the number of ambulances handover delays at emergency departments increased from 86,003 in November – March 2013/14 to 139,970 for the same period in 2014/15 [Link](http://www.england.nhs.uk/statistics/statistical-work-areas/winter-daily-sitrep-2013-14-data-2/).
In 2012/13 the intense public scrutiny culminated in a Health Select Committee inquiry\(^2\) and this scrutiny has continued. The pressure of increasing demand has more recently been exacerbated by acute shortages of associated healthcare professionals particularly in emergency medicine,\(^3\) primary care\(^4\) and ambulance paramedics.\(^5\)

It is increasingly recognised that provision of urgent care is a complex system of interrelated services and that this whole system approach will be key to improvement and development in the future. In response to the clear pressure within the emergency and urgent care system, in 2012 NHS England embarked on a major review of urgent care services and in 2013 set out their strategy for development of a system that is more responsive to patients’ needs, improves outcomes and delivers clinically excellent and safe care\(^6\). The challenge now is to find ways to put this “blueprint” in to practice.
Figure 1 Selected key developments and policy initiatives for the delivery of emergency and urgent care
Knowledge about the current evidence base on models for provision of safe and effective urgent care can support this process. The purpose of this rapid review is to examine what evidence there is on how efficient, effective and safe urgent and emergency care services can be delivered within the NHS in England, the quality of that evidence and the gaps in evidence which may need to be addressed.

**Hypotheses tested in the review (Research Questions)**

The NHS England review\(^6\) has set the agenda for urgent care with recommendations on how the urgent care system and the services within it need to change. We have used the key themes identified in this review as the framework for this rapid evidence review to provide both focus and context for evidence appraisal and the identification of evidence gaps which will be of direct relevance to future developments. The five key themes identified in the NHS England review are:

- providing better support for people to self-care;
- helping people with urgent care needs to get the right advice in the right place, first time;
- providing highly responsive urgent care services outside hospital so people no longer choose to queue in A&E departments;
- ensuring that those people with more serious or life-threatening emergency care needs receive treatment in centres with the right facilities and expertise, to maximise chances of survival and a good recovery; and
- connecting all urgent and emergency care services so the overall system becomes more than the sum of its parts.

The first theme focussed on providing better support for people to self-care encompasses the much broader areas of healthcare related to reducing the need for urgent care. This theme warrants a separate review as it involves complex issues such as management of long term conditions, health promotion and injury prevention. As it targets alternative healthcare provision outside of urgent care the potential scope was considered too broad and diffuse to be included within the constraints of this review. We have therefore excluded this theme and concentrated on the other four themes directly related to delivery of urgent care.
Within each of these four key themes the NHS England review sets out more specific proposals for service change and delivery and these will form the focus of the primary scope for individual elements of the review. We have also added an additional underpinning theme not identified as a separate issue by the NHS England review. In order to develop services that are responsive to the needs of the population using them it is essential to understand the characteristics and drivers which underpin demand for services and the choices people make about how they use those services. Without this it is difficult to ensure alignment between service development and patient need. We will therefore include within our review a brief overview of a fifth theme focussed on patterns and characteristics of the demand for urgent care (including change over time) and the factors that influence decisions about when and how to access urgent care.

Although these key themes provide focus each one potentially still potentially includes a range of issues. To keep the review process manageable within the time and resources available we have therefore restricted the research questions for some themes to a particular service area highlighted as of particular importance in the NHS England review.

**Research questions:**

The research questions examine the evidence relating to the following:

1) To what extent does evidence on existing and proposed approaches to the delivery of urgent care support the development of four key themes in the NHS England review of urgent care?

- helping people to get the right advice in the right place, first time – this theme could potentially cover a range of services in terms of what care is eventually accessed. However, the process of providing advice and directing people to the right service when they first try to access care is firmly grounded in the NHS England review as the NHS 111 telephone service. This service is seen as the gateway to directing requests for emergency care to the right service. We have therefore focussed on telephone based access services in this review.
• providing highly responsive urgent care services outside hospital – this theme also potentially includes a range of community based services. However it was beyond the scope of this review to search and synthesise all of the potential literature about community based urgent care. The 2013 NHS England review and related action plan make a clear statement that the ambulance service is considered a key provider in achieving this objective. We have therefore focused on the evidence for developing the ambulance service to manage more people in the community setting in this review.

• ensuring that people with serious or life-threatening emergency care needs receive treatment in appropriately staffed and resourced facilities; this theme is concerned with the provision of Emergency Department (ED) care, both major regional facilities and local ED’s. There is already a substantial evidence base about the impact of providing regionalised services (e.g. for stroke, heart attack) so there is no value in repeating this here. Furthermore, service pressure is greatest in general emergency departments (and major regional facilities also function as “local” ED’s). We have therefore focused this review on the evidence about different models and processes for delivering ED care to keep the review relevant to current NHS challenges.

• connecting urgent and emergency care services – the NHS England review sets out a clear view that the way to achieve this objective is the development of urgent care networks to develop and manage local urgent care systems. We have focussed this element of the review specifically on evidence about models of urgent care networks.

2) What is the evidence on characteristics of demand for urgent care and why and how people access urgent care that may help future service planning?

We have conducted and reported a rapid review for each of these 5 themes. For each review we have considered 2 additional questions;

3) What is the quality of that evidence?

4) What are the main/significant evidence gaps?
Chapter 2 - Review methods

Overview of rapid review methods

This was a rapid framework-based evidence synthesis which needed to be completed within a relatively short timeframe of 6 months to produce a review which met HS&DR needs. We have used rapid review methods to ensure the efficient identification and synthesis of the most relevant evidence. The multiple dimensions covered by the review questions posed a considerable challenge to the rapid review process. This challenge was further complicated by the fact that emergency and urgent care does not involve discrete populations or conditions but encompasses whole populations and a heterogeneous mix of conditions and acuity and care is delivered by a range of services. As a consequence there was a potentially huge pool of related literature.

Given the large scope and time and resource constraints we have not taken a standard approach to this review. Our aim was to provide a broad overview of the existing evidence base for each theme and any associated limitations. We have therefore applied the following criteria to structure the review process.

We have concentrated on identifying and synthesising the key evidence using a focused, policy relevant framework to keep the task relevant and manageable. Framework-based synthesis has been identified as an efficient method for synthesising evidence to inform policy within relatively tight time constraints.

- The review did not attempt to identify all relevant evidence or to search exhaustively for all evidence that meets the inclusion criteria. Instead we have used a structured searching approach to identify the key evidence.
- The data extraction and quality assessment have focused on the most critical information for evidence synthesis rather than aiming to exhaustively extract and critique all the available information in individual papers.
- We have not appraised the evidence in terms of how future services should be provided or make recommendations about service configuration.

Framework

As the focus of this review is on models of care, that is service and system delivery, we have not search for, or considered, evidence related to specific clinical interventions for specific conditions. We have also only included primarily evaluative research of actual interventions.
(although the definition of intervention can be broad and consider changes to organisation, changing professional roles, new services etc.) in order to provide an overview of what may or may not work in practice. For this reason we have purposely excluded the more theoretical literature, for example relating to organisational behaviour, professional development and clinical competence, work psychology, patient decision making and behaviour. Where additional review in these related areas is of value these have been highlighted in the individual review chapters as specific areas for further in-depth review and analysis.

For each of the four themes related to the NHS England review we have considered three main areas:

- Evidence on efficiency and effectiveness (including cost-effectiveness) of service delivery for any identified operating models including individual service and whole system perspectives.
- Evidence on associated workforce issues where this is primary research evaluating the effectiveness of changing or developing new professional roles in the delivery of urgent care and workforce planning.
- Evidence on any related patient experience outcomes.

Urgent care provision in England is a rapidly changing environment. The NHS England review has prompted a range of work programmes and professional bodies, for example the Royal College of Emergency Medicine regularly publish recommendations about delivery of services. Where relevant we have used key policy documents published before October 2014 specifically related to the implementation of the NHS England reform of urgent care to develop the review framework.

The additional fifth theme on understanding demand and use of services has focused on primary research that;

- Reports analysis of not just amount of demand but the characteristics of that demand (for example age profiles, condition profiles, whole system demand for different types of service), and
- Reports patient derived explanatory research concerned with decisions to access urgent care.
This framework has provided a clear structure to guide the review whilst retaining flexibility that has allowed development for each individual theme in terms of defining the scope of the search strategies, defining inclusion and exclusion criteria to specify what types of studies will be included in each theme and evidence synthesis.

**Search Methods**

A variety of search methods were undertaken in order to identify relevant evidence for each of the review questions and themes in a timely fashion. We have used a number of different search strategies for this review but using a general structure of combining relevant terms such as:

- **Population** - users of the range of services within the emergency and urgent care system (ambulance services, ED, other urgent care facilities, telephone access services, primary care urgent care services).
- **Outcomes** - **Processes** - ED attendances, emergency admissions, ambulance calls, dispatches or transports, demand, appropriateness of level of care, adverse events. **Patient outcomes** - patient experience and satisfaction, decision making, cost consequences and cost-effectiveness.

Searches were conducted in two stages;

**Stage One – General search on Medline**

**Stage Two – Targeted database searches around telephone triage, ambulance, demand, organisation of emergency departments and networks.** To increase efficiency, where appropriate we have utilised existing search strategies from related research we have conducted within ScHARR or from existing related systematic reviews.

**Database search strategies:**

**General search**

An initial broad scoping search was conducted on Medline. This broad search aimed to find studies that evaluated the impact of changes in organisation, policy, structure and systems on...
urgent care. Descriptive studies without an evaluative component were not considered relevant. Key issues for consideration were access to services, appropriate management of patients, service delivery, models of delivery and clinically appropriate management of patients. The general search strategy used a combination of free text and Medical Subject Headings (MESH) and also appropriate subheadings. A detailed description of the search strategy is provided in Appendix 1. The search retrieved a large number of results and refinements were made to the search to reduce the number of results. One key modification was the removal of the term “ambulatory care” as this term retrieved a large volume of results related to outpatient rather than urgent care. The final search retrieved 9488 results. After careful discussion it was decided that due to time constraints a sample 20% would be considered for inclusion for this search and further targeted searches conducted relevant to each of the 5 themes. For the 20% sample of the general search potential inclusions relevant to the 5 themes were identified using key words and any additional references identified from this search and not identified in the targeted search were added to the list of potential inclusions for that theme.

Targeted searches
For the targeted searches the following databases were searched: Medline via OVID SP, EMBASE via OVIP, Cochrane Library via Wiley Interscience, Web of Science via Web of Knowledge and CINAHL via EBSCO. Searches were limited to publication date from 1995-Current in order to keep results relevant to current services, and English Language only. All searches were completed October 2014 to January 2015. A detailed description of each of the targeted search strategies is provided in Appendix 1. Targeted searches were conducted on the following areas, telephone triage; ambulance services; re-organisation of emergency departments; developing and building urgent care networks and demand for emergency and urgent care services.

Telephone triage
Within ScHARR extensive previous work had already been completed on telephone triage and we were able to rerun an existing search strategy for this review with expansion of the dates from 1995-Current. After deduplication there were 1127 unique references.
Ambulance services
The search on ambulance services focussed on finding literature around the impact of ambulance services treating people at home where appropriate and triaging them to more appropriate community or primary care services. Additionally, research was sought on developing the skills of ambulance personnel to enable them to perform extended roles. After deduplication there were 4499 unique references.

Organisation of emergency departments
Targeted searches were also conducted on re-organisation of emergency department. Targeted searches were conducted to find evaluative literature on service delivery following re-organisation of processes within the emergency department. After deduplication there were 3539 unique references.

A recent report by the Royal College of Emergency Medicine\(^9\) recommended that all emergency departments should have a co-located primary care service. We identified an existing, relevant rapid evidence review conducted by the University of Warwick\(^10\) and therefore updated the search strategy described in this review. After deduplication there were 5724 unique references for this search.

Networks
Another targeted search focused on the development and use of networks within Emergency and Urgent care. After deduplication there were 1301 unique references.

Demand for emergency and urgent care
The searches around demand for emergency and urgent care were based on searches previously completed for a project ScHARR conducted for the NHS Confederation in 2013 and were expanded to the full range of dates and databases. The search aimed to retrieve empirical research on urgent care demand, research on rising demand in the ageing population and empirical research on patient derived reasons for accessing different emergency or urgent care services. After deduplication there were 1371 unique references.

The search results were downloaded into Endnote X7.2.1.
Given the scope within each search and limited time we were not able to conduct extensive supplementary searching, for example citation searching. However, in addition to the database searches we also identified key evidence by:

- Scrutinising reference lists of included relevant systematic reviews.
- Utilising our own extensive archives of related research including a number of related evidence reviews.
- The evidence review that NHS England produced as part of their consultation.
- Consultation with internal ScHARR topic experts and some external topic experts.

Review process

Inclusion and Exclusion Criteria

We have included both quantitative and qualitative empirical evidence in the review where relevant to one of the five themes. Both UK and international evidence have been included to ensure alternative models of urgent care delivery designed to address the same objectives set out in the NHS England review (for example, reducing ED attendances) are considered. We have only included published peer reviewed evidence in order to ensure we have synthesised evidence which has already undergone methodological and expert scrutiny. Emergency and urgent care changes rapidly both in terms of demand, clinical care and service delivery so we have limited included evidence to the years 1995 – 2014 to ensure the evidence assessed has context and relevance to current policy and practice. Evidence for specific clinical interventions and conditions has been excluded as this is likely to be substantial for a large number of conditions and our focus is whole services rather than narrow condition specific populations. However we have included evidence for defined but broad (in terms of condition) populations, for example children or the frail elderly. To summarise, we have used a core set of inclusion and exclusion criteria for all 5 themes to ensure consistency in the review approach.

Inclusion criteria:

- Empirical data (all study designs)
- Emergency/urgent care
- Report relevant outcomes
• Written in English
• Published between 1995 – 2014

Exclusion criteria:
• Descriptive studies with no assessment of outcome
• Opinion pieces and editorials
• Non-English language papers
• Conference abstracts

Additional theme specific inclusion and exclusion criteria were then applied in addition to the core criteria. Theme specific criteria are described in each review chapter.

Data Extraction
Data extraction of included papers was undertaken for each theme. However, given the number of themes and scope within each one we could not complete detailed and exhaustive data extraction for all relevant inclusions. To make this task manageable, ensure consistency across the themes and enable comparisons to be made between themes we employed two strategies;

1. For each theme we used any existing, relevant systematic reviews identified from the searches as the starting point for decisions about which individual identified papers meeting the inclusion criteria we would extract data from. We did not extract data from individual papers already included in relevant systematic reviews. Instead we extracted the data from the systematic reviews in to summary tables. Any additional papers not included in the systematic reviews had data extracted in to summary tables.

2. All data extraction was carried out directly in to summary tables rather than detailed data extraction forms which would subsequently require summarising. Included research was highly heterogeneous and so we used a simple, broad template to summarise the key characteristics and findings from each included systematic review or individual paper. For each paper we summarised the study design used; population and setting; main purpose and objectives including outcomes measured and key findings and conclusions.
Quality Assessment

Rather than using a standard checklist approach we have focused on an assessment of the overall quality and relevance of the evidence included within each theme in the review. Relevance has been assessed based on factors including the number of relevant studies, particularly systematic reviews, study types and design, the country and health system the research was conducted in and whether the research is single centre or multi centre. Quality has been assessed based on study types, the strength of the evidence identified by related systematic reviews and other key factors. For each theme we have provided a narrative commentary on quality and relevance that will allow readers of the rapid evidence synthesis to make an assessment of the rigour and relevance of evidence included in the review.

We have effectively conducted five separate rapid reviews, one for each of the 5 themes set out in the research questions. We have therefore presented each review separately, describing any methods specific to that review; results; an appraisal and summary of the existing evidence and any identified evidence gaps identified which are likely to be critical to further development of the main urgent care delivery objectives related to a theme. This includes where additional, more detailed topic specific evidence review could be of value or where more primary research is needed, for example on a larger scale to provide definitive evidence of effectiveness.

The five reviews are presented in chapters 3 – 7.

A summary of all the reviews together with an appraisal of common evidence across themes to provide a more comprehensive overview that describes, compares and contrasts different approaches to the delivery of urgent care together with a headline summary of key findings is presented in chapter 8. This review has been designed to identify evidence gaps and help inform future NIHR HS&DR programme research priorities. As such the analysis has been undertaken using a research commissioning rather than service commissioning perspective.
Chapter 3 - Trends and characteristics in demand for emergency and urgent care

Introduction

The main focus of this rapid review is assessment of the evidence relevant to the NHS England review of urgent and emergency care. However, to provide context we have presented a short overview of the current state of knowledge around the characteristics and drivers which underpin demand for services. This may be of use for future planning and the ability to develop services that are responsive to the needs of the population using them and ensure alignment between service development and patient need and so is of relevance to the later review about urgent care networks.

Increases in demand for Emergency Department care are well documented. In England, demand for ED care doubled from an estimated 6.8m first attendances at type 1 (24 hour, consultant led service) EDs to 13.6m over the 40 years from 1966/67 to 2006/7 - equivalent to an increase from 138 to 267 first attendances per 1000 people per year. Since 2006/7 attendances at type 1 EDs have further increased to 14.3m in 2012/13 and at the same time there has been a rapid increase in the use of minor urgent care services (type 3 – not 24 hours, may be run by nurses or GP’s, limited facilities such as X-ray) with attendances increasing by 46% from 4.7m in 2006/7 to 6.9m in 2012/13. Similarly, demand for 999 ambulance services has also steadily increased from around 4 million calls per year in 1994/5 to 9 million in 2012/13 – an increase of 160% with utilisation rising from 78 to 171 calls per 1000 people per year over the same time period. People with health problems also access urgent care via NHS 111 and primary care but NHS 111 is a relatively new service and there is a lack of national data on urgent care contacts with primary care so it is difficult to assess whole system demand for emergency and urgent care in England.

More detailed analysis of UK trends in demand is available in reports from the NHS Confederation and Nuffield Trust. Here we have examined the empirical evidence that may help explain why demand is changing.
Methods

The main inclusion and exclusion criteria, search strategies and review process have been described in Chapter 2. We have conducted previous reviews in this area and are aware of the relative scarcity of related evidence. In addition this topic area is not concerned with interventions or service delivery and hence processes or patient outcomes. We have therefore included literature reviews which were not systematic reviews but which have described a structured search strategy. Search dates were from 1995-2014. For this review specific additional inclusion and exclusion criteria were studies investigating:

Inclusion criteria

- Trends in demand for emergency and urgent care over time
- Analysis of characteristics of demand
- Empirical, patient based studies examining reasons why people access emergency and urgent care how they choose which service to access.

Exclusion criteria

- Studies of demand that describe volumes of activity only at single points in time

Review process

Studies were identified from updated and expanded database searching using a search strategy from one of our own previous reviews in this area and a review of the evidence on callers to the 999 service with primary care problems from an NIHR Doctoral Research fellowship currently awaiting publication in the NIHR journals library (Dr M Booker, University of Bristol, personal communication). As this aim of this part of the review was to describe an overview of current evidence to provide context for the more detailed rapid reviews on service delivery we limited the studies included in three ways:

We have conducted a previous scoping review of potential reasons for increases in ambulance demand and as this is already in the public domain and available for reference we have not considered papers included in this review.13

1. We did not conduct a double 10% random sift of the results of the database searches.

These were sifted by one reviewer (JT) and supplemented by potential inclusions identified in the 20% random sample from the general search, also sifted by the same reviewer.
2. Data extraction of individual papers meeting the inclusion criteria was only conducted for papers not included in relevant review papers identified in the searches.

The results of the review sifting process are given in Figure 2.

Results

We identified 4 relevant systematic or rapid reviews an additional 39 primary studies not included in the systematic reviews 8 relating to demand and 31 patient based studies exploring reasons and choice in accessing urgent care. The characteristics and findings of the included reviews and primary studies are summarised in tables 1 - 3.

<td>Amiel, 2014 &lt;sup&gt;28&lt;/sup&gt; UK</td>
<td>Survey using self-completed patient questionnaires</td>
<td>Patients presenting to open access urgent care centre attached to ED providing urgent care normal GP services without appointment</td>
<td>To explore why patients with minor illness choose to attend an urban urgent care centre for their healthcare needs.</td>
<td>649 participants. Median age 29 years. 72% were registered with a GP; more women (59%) attended than men. The majority of participants rated themselves as healthy (81%). Access to care (58%) and expectation of receiving prescription medication (69%) were main reasons for attending ED. GP dissatisfaction influenced 10% of participants decision to attend an urgent care centre. 68% did not contact their GP in the previous 24 h before attending. Young adults mostly registered with a GP used urgent care centres because of convenience and ease of access rather than satisfaction levels with their GP.</td>

<td>Norredam, 2007 31 Denmark</td>
<td>Quantitative, questionnaire survey of walk-in patients and care providers at four Copenhagen ERs.</td>
<td>General Emergency Department (n=4); Migrant and national citizen usage of ED. (n=3426). response rate 54%.</td>
<td>To investigate the extent to which immigrants and patients of Danish origin have different motivations for seeking emergency room (ER) treatment, and differences in the relevance of their claims.</td>
<td>Groups of foreign origin are more likely to consider contacting primary care providers before attending ED. A higher number of immigrants were unable to access primary care and immigrant ED attendance was often due to not being able to access primary care. In contrast, more national patients claimed that the ED was more relevant for their needs. Patients from non-western or middle eastern origin were significantly more likely to attend ED because they did not live locally and could not access their normal primary care giver. Care providers reported that 21% of all ED attendances were not relevant to ED and a significantly higher proportion of non-western or middle eastern patients had irrelevant ED visits and irrelevant ED attendance was significantly related to not being able to access primary care.</td>

<td>Campbell, 2006 Scotland UK</td>
<td>4 Focus groups and 51 in-depth interviews with 78 participants</td>
<td>Patients aged between 45 to 64 years in eight urban and rural general practices in Northeast and Southwest Scotland.</td>
<td>To explore whether and how patients' consulting intentions take account of their perceptions of health service provision.</td>
<td>Anticipated waiting times for appointments affected consulting intentions, especially when the severity of symptoms was uncertain. Strategies were used to deal with this, however: in cities, these included booking early just in case, being assertive, demanding visits, or calling out-of-hours; in rural areas, participants used relationships with primary care staff, and believed that being perceived as undemanding was advantageous. Out-of-hours, decisions to consult were influenced by opinions regarding out-of-hours services. Some preferred to attend nearby emergency departments or call 999. In rural areas, out-of-hours care and perceived barriers to its use, including the use of the telephone and travelling at night. Participants preferred contact with a familiar doctor and were distrustful of telephone advice, particularly from nurses. Older people appear reluctant to make use of out-of-hours services and are critical of the trend away from out-of-hours care being delivered by a familiar GP.</td>

<td>To investigate why patients with minor problems and a primary care physician (PCP) present to the ED. Results compared those attending in weekdays day-time (WDD) and those not attending during weekday-daytime (NWDD)</td>
<td>There were high levels of self-perceived urgency for treatment, a strong majority felt they could not wait 1-2 days for treatment. More WDD patients felt their case was too difficult for the PCP to handle as opposed to NWDD patients. Around 24% of patients in both groups felt they needed to be admitted to hospital. 70% of WDD patients were willing to contact their PCP, despite 45% feeling their condition was too complex for their PCP, 45% did not contact PCP at all. 60% of patients across both groups felt the ED was more convenient than their PCP.</td>
</tr>
</tbody>
</table>
Summary of findings

This review has been conducted to provide a brief overview and context for the subsequent more detailed reviews. We have therefore only identified key themes that have emerged from the available evidence.

Trends and characteristics of demand for emergency and urgent care

We identified 4 review articles and 8 primary studies that have explored trends in demand and associated characteristics. One review\textsuperscript{17} and 2 primary studies\textsuperscript{23,24} only considered older populations. Two studies\textsuperscript{16,22} were concerned with emergency ambulance utilisation, seven focused on ED attendances and one\textsuperscript{25} ED and GP out of hours. The key common themes that emerged were:

- The trend of increasing, year on year demand for emergency and urgent care is consistent across developed countries. Population utilisation rates are also increasing and this appears to be greater for ambulance services than EDs.

- Population and demographic changes explain some but not all of the increases in demand. Elderly people do utilise emergency and urgent care more frequently, particularly those aged >80yrs and are more acutely unwell but this group only accounts for about 25\% of increased demand. Impact of ageing populations may also vary by locality and the relative health and socioeconomic status of the resident elderly population.

- Demand is likely to be influenced by a range of other characteristics and factors including health needs (chronic conditions, acute illness, drug and alcohol dependency); socioeconomic factors (isolation and loneliness, lack of social support, deprivation); patient factors (decision making behaviours, awareness, expectations, convenience) and policy (insurance coverage, numbers of hospitals, access to primary care, geographical differences in provision) but there has been little research examining the association between the rise in demand and these factors.

- There have been few attempts to identify and map the different influences on demand and the relative influences of each factor to create a comprehensive profile of the different health care needs of populations accessing emergency and urgent care to inform health service planning.
• There is a lack of population based studies, identification of independent risk factors associated with accessing urgent care and whole system (rather than individual service) demand studies. This is particularly constrained by a lack of information about urgent care within the primary care setting and modelling studies that can forecast likely future changes in demand.

Patient based studies examining reasons for accessing emergency and urgent care

We identified 38 relevant studies from the database searches, seven of which were included in the 4 systematic reviews and so are not included in the summary table. Of the 31 studies we have examined in more detail, 16 were qualitative interview or focus group studies, 12 were surveys and 3 used mixed designs. The majority (23/31) were conducted in the ED, predominantly with patients presenting with urgent rather than emergency conditions, 2 were with ambulance patients and 6 were in other settings such as GP surgeries and urgent care centres. A number of frequent and common themes emerged from these studies concerning reasons why patients used emergency or urgent care and their choice of where to access care.

• Access to and confidence in primary care focused highly. Factors identified included lack of awareness of options, particularly out of hours services, dissatisfaction with GPs, limited opening hours, anticipated waiting times for appointments, previous experience using OOH and perceived barriers. The elderly in particular did not like or trust telephone based out of hours services. In many studies a high proportion of patients attending ED were registered with GPs but still chose to access ED instead.

• Perceived urgency, anxiety and the value of reassurance from emergency based services.

• Being advised to attend ED by family, friends or healthcare professionals.

• A belief that their condition needed the resources offered by a hospital including hospital doctors (rather than GPs), diagnostics, particularly x-rays, and treatment.

• In some health systems, costs and transport options affected decision making.

• Convenience in terms of location, not having to make appointment and opening hours. Older people were more likely to contact a GP first but younger patients contact urgent care centres, ED or out of hours as they find this more convenient.
Conclusions

Despite serious concerns about rising demand and the impact this has on health services, there is remarkably little empirical evidence that can fully explain why this has occurred. The evidence included here has highlighted a range of factors that may influence demand but much of the research has focused on either individual services or populations such as the elderly. Most of the evidence presented here has come from Australia and there were no UK studies. There is scope to replicate some of the Australian studies using UK data.

The 4 review articles helpfully brought together a broad literature of discrete studies on individual factors that may influence demand and there is a substantial patient focused literature that has examined the reasons why people choose to use emergency and urgent care and how they decide which service to access. The evidence gaps and challenges identified from the existing evidence are to:

- Examine demand from a whole system rather than single service perspective and gain better understanding of the relative proportions of demand for different parts of the system and the characteristics of patients within each sector. This more detailed understanding would allow more accurate assumptions to be made about changing care delivery, for example what is a realistic proportion of patients who could be managed out of hospital.

- Build on the existing knowledge about the range of factors which may be influencing demand and develop more sophisticated research studies that can comprehensively map these issues in to a coherent model. The conceptual model described in the review by He\textsuperscript{15} is a useful starting point.

- Explore the relationships and associations between individual influences and demand so that the relative contribution each one makes can be assigned to a map or model. This would then support the development service design and planning to meet the needs of local populations\textsuperscript{19} and the development of predictive models that can be used to estimate likely changes in population needs for emergency and urgent healthcare\textsuperscript{22}.

- All of these will require the development of robust, system wide information systems to support these complex functions.
Chapter 4 - Telephone triage and advice services

Introduction

A key principle of the NHS England urgent and emergency care review is provision of a telephone based service that can act as a gatekeeper and direct people with urgent care needs so that they can get the right advice, in the right place, at the first point of contact. NHS 111 is the cornerstone to this function and already provides a free, national, 24 hour telephone based service to triage, assess and signpost requests for urgent healthcare. However, the introduction and implementation of NHS 111 has not been without problems and the NHS England review recognises the need to substantially enhance this service in order to deliver the intended benefits within the wider urgent and emergency care system. We have reviewed the broader evidence on use of telephone based triage and advice services for access to and management of urgent care in order to summarise the current state of knowledge and identify evidence gaps which may need to be addressed to enable further development of this key service.

Methods

The main inclusion and exclusion criteria, search strategies and review process have been described in Chapter 2. Search dates were 1995-2014. For this review specific additional inclusion and exclusion criteria were;

Inclusion criteria:
- Requests for emergency/urgent care
- Telephone triage/ advice/ consultations
- Report relevant outcomes (identified below)

Relevant outcomes related to:
- Efficiency (triage accuracy; waiting times; adherence/compliance; other service impacts e.g. reduction in ED visits)
- Effectiveness (safety; unplanned health service re-contacts; patient outcomes; cost)
- Patient experience (satisfaction; acceptability; appropriateness; experience; access)

Exclusion criteria:
- Telephone services for single conditions
- Telephone services for non-urgent advice

**Review process**
Studies were identified from database searching and through expert knowledge of the field of interest. In addition to the studies identified through database searching the study team were aware of 10 additional studies and these were assessed for inclusion in this review. The results of the review sifting process are given in Figure 3. A randomly generated 10% sample of studies from the database searches (n=124) was double sifted by another member of the study team. The reviewers initially agreed on inclusion or exclusion for 88% of studies and agreed to exclude the remaining 10 studies after discussion. 87 papers were included in the review, representing 83 individual studies.
Figure 3 PRISMA flow diagram for telephone triage and advice services searches

Records identified through database searching
(n = 1124 after duplicates)

Additional records identified through other sources
(n = 10)

Records included
(n = 1134)

Records screened
(n = 1134)

Records excluded
(n = 992)

Full-text articles assessed for eligibility
(n = 142 (132 database; 10 other))

Full-text articles excluded, with reasons
(n = 55 (52 database; 3 other))
Eligible full text articles included within systematic reviews (n = 33)*

Papers included in synthesis
n = 54
(10 systematic reviews
44 primary research)
**Systematic reviews included**

87 papers representing 83 studies were included in this review. 8 were systematic reviews. The results from the 8 reviews (10 papers) are shown in Table 4. Many of the references included in the reviews overlapped. This overlap is shown in Table 5. Formal data extraction was not undertaken for the 33 papers meeting the inclusion criteria and included in systematic reviews as this would have been conducted during the review process. Table 6 lists these 33 papers (32 studies) and which systematic reviews they were included in. 42 studies (43 papers) did not feature in any of the included systematic reviews and underwent full data extraction (Table 7).

<td>Blank, 2012 UK 57, 58</td>
<td>Systematic review and narrative synthesis using rapid evidence synthesis methods.</td>
<td>In and OOH; Primary and Urgent; Nurse (49/52 papers)</td>
<td>To synthesis of evidence of the appropriateness of and compliance with different types of telephone triage advice</td>
<td>Triage decisions rated as appropriate varied between 44–98% and compliance ranged from 56–98%. Variation could not be explained by type of service or method of assessing appropriateness. Triage decisions to contact primary care may have lower compliance than decisions to contact emergency services or self-care.</td>
</tr>
<tr>
<td>Purc-Stephenson, 2012 Canada 59</td>
<td>Meta-analytic Review. Compares Compliance rates by type of advice (attend ED; office care (GP); self-care)</td>
<td>In and OOH; Primary and Urgent; Nurse</td>
<td>To investigate if patients comply with triage advice from tele-nurses and to identify factors that may influence compliance</td>
<td>13 studies were included. The overall compliance rate was 62%. Compliance by type of advice was: use emergency services (ES) 63.08%; office care/GP (OC) 44.14%; self-care (SC)78.92% ES vs OC OR: 2.68, 95% CI 1.77 – 4.04; SC vs OC OR 3.30 (95% CI 2.18 – 4.99). Main reasons for non-compliance were recall problems, symptom change and accessibility to services. Non-compliant patients used lower intensity of care than advised.</td>

### Staff type comparisons

7 studies (9 papers) reported on telephone triage performed by different staff types. There was 2 RCTs, 1 was a controlled trial, 3 prospective observational studies and 1 retrospective study.

Two studies compared the appropriateness of nurse telephone referrals compared with other referral sources. Both studies found that GP or physician Emergency Department referrals were more appropriate than either nurse telephone referred or self-referred patients, when measuring appropriateness using clinical criteria.

Two studies directly compared Nurse and Doctor telephone triage. One study reported that nurses were more likely to recommend higher intensity advice than Doctors, but that when the appropriateness of this advice was reviewed by experts the nurse advice was more likely to be appropriate. The other study found that callers were significantly more likely to be satisfied if their call was dealt with by a Doctor than a nurse and have higher compliance rates, whilst repeat calls for advice were significantly higher in the nurse group at both 4 hour and 72 hour time intervals. A different study looked at introducing second level physician triage in a nurse telephone system. Adopting this approach halved the number of out of hours referrals.

One study looked at using telephone advice given by nurses and paramedics for low urgency ambulance services. They found that nurses were more likely to triage calls as not requiring an ambulance. The 330 cases triaged by a nurse or paramedic as not requiring an

</table>
emergency ambulance were less likely to attend ED but 9% of these patients were admitted to a hospital bed. The only included study of a service using non-clinical call handlers supported by clinicians was the evaluation of NHS 111 pilot sites but no comparison was made of decision making by non-clinical call handlers and clinicians.

Safety
18 studies reported on safety of telephone triage. The related systematic review by Huibers included 10 of the papers identified in this review and reported that a high proportion (97%) of all out of hours telephone triage contacts were safe but that the proportion of safe contacts decreased when looking at high urgency patients. From 10 studies using high-risk simulated patients the authors found that just 46% were safe, bringing into question whether telephone triage and advice is as safe for higher urgency patients.

Of additional studies not reported in the Huibers review, one study also found that more safety issues were associated with higher urgency calls, and two studies, one set in primary care and one set in EMS care both reported no adverse outcomes or differences in sub-optimal outcomes for high urgency calls.

One study looked at characteristics of calls coded as low urgency that resulted in death. The authors found that these calls related to older people who did not make the call themselves. The calls were short, did not always conform to the system protocol and non-life threatening symptoms were reported. This concurs with the findings from a primary care based study which found that telephone consultations were shorter and did not include sufficient information to exclude serious illness. However, a study by Snooks reported that the overall proportions of patients who receive insufficient advice was low (1.4% - 3.3%). Based on the information from a study which analysed the incident reports from errors, 25% of errors related to incorrect assessment.

Compliance
21 studies reported on compliance with telephone triage advice recommendations. There were also two systematic reviews that reported on compliance (Blank, Purc-Stephenson) and these reviews contained 13 of the studies identified in this review. Blank reported that compliance ranged from 56–98% and Purc-Stephenson reported an overall compliance rate of 62% but that compliance rates differed by the type of advice received, with 63% complying with advice to attend A&E, 44% complying with a primary care referral and 78% complying with advice to
advice. Of the studies not included in the systematic reviews, three studies reported compliance that was within the range identified by Blank et al. The one study identified a 20% refusal of telephone triage recommendations, whilst another reported that callers may interpret advice differently from how it is intended, resulting in unintentional non-compliance. Compliance with advice provided by callers to NHS 111 was 86%. A qualitative study reported that compliance may be improved when callers feel involved in the decision making.

**Satisfaction**

Twenty two studies reported satisfaction data. Satisfaction with telephone triage and advice services ranged from 55% - 97%. Dissatisfaction ranged from 2.3% - 18.3%. Dissatisfaction was higher for EMS based studies where patients may have expected to receive an ambulance and instead received telephone advice. Qualitative research suggests that patients value feeling involved in the decision making, if the manner of the call handler is calm, friendly and respectful and that patients feel it is a useful backup service where they can avoid being labelled as ‘time wasters’.

Where telephone advice provided by different staff types was compared, patients reported less satisfaction with nurse led services compared to doctor led services.

**Costs**

9 studies reported costs or cost savings. The most common method of calculating and reporting costs was to report costs saved from callers change in subsequent health care seeking behaviour as a result of the call. These were not consistently reported and were reported as average per patient savings; cost savings per call recommendation type; annual net savings and overall reduction, making comparison difficult. Two studies reported costs related to introducing a nurse telephone line for low urgency ambulance patients. One of these studies reported a cost reduction of £4,520,000 from reduced ambulance dispatch and one reported reductions in costs due to reduced ambulance cycle times and fewer admissions to hospital. Only one study reported a cost increase and this related to the cost of the General Practice telephone bill after the introduction of a telephone service. A cost consequence analysis conducted as part of the evaluation of NHS 111 pilot sites estimated the service might potentially save the NHS £2.4 million a month although this was based on limited cost data and considerable assumptions.
Service impacts

Seventeen studies reported impacts on their own service or other services, either from increased or reduced service use and or increased or reduced staff workload.69-71, 87, 96, 99, 100, 102-104, 106, 110, 113,115,123, 127, 135 One study found that NHS Direct referred a higher proportion of patients to other services when compared to general practice.135 An RCT by Lattiimer reported a 38% reduction in primary care appointments and a 23% reduction in home visits69, whereas another study reported no change in primary care appointments but home visits reduced by 18%.71

A number of studies reported that Doctor workload fell after the introduction of a telephone service. One study reported a reduction in workload of 54% compared to the previous 3 months 70 and that nurses were able to handle 26% of requests for GP appointments by telephone, whilst another study reported a 39% reduction in demand.87 However, other studies have found that whilst a telephone advice service may reduce demand for face to face appointments in the first instance, patients consult their GP more frequently in the subsequent weeks.96 In particular, older patients were more likely to have follow up contacts after receiving telephone advice.115 The evaluation of NHS 111 pilot sites found no impact on attendances at ED and contacts with urgent primary care services but a statistically significant increase in ambulance incidents.106

Five studies found that the introduction of a telephone advice service for low urgency ambulance service patients resulted in fewer ambulance responses being required.100,102-104, 113 However some studies reported high call return rates, where calls are passed back for an ambulance response or that not as many calls as expected could be resolved by telephone.102, 103

Accuracy and appropriateness

Twenty six studies reported data on the appropriateness or accuracy of telephone triage and advice services. The systematic review by Blank 57 also reported on appropriateness and 11 of the studies identified here were also included in the review by Blank.74, 76-78, 81-83, 85, 89, 91 This review identified that triage decisions rated as appropriate varied between 44–98%. However many different definitions of appropriateness were used and this leads to difficulty when trying to compare results.

From the 15 other studies73, 90, 101,102,116- 120, 125, 132, 136,139-141, four studies looked at the appropriateness of ED referrals. In terms of referral sources, no difference was found
between telephone and self-referred patients but that doctor referred patients were the most appropriate referrals. One study identified 33% of ED referrals as non-essential and another identified that a high proportion of ED referrals should be handled in primary care.

Most studies reported that a high proportion of referrals were appropriate and these were often in excess of 90%. Triage advice and referrals were more likely to be unnecessary rather than insufficient. However, one study identified that acute and non-urgent scenarios were more likely to be classified correctly than urgent. Where low urgency ambulance calls were passed for telephone advice there was a high return back rate for an ambulance response.

**Quality**

There is a large evidence base on telephone triage and advice, but studies are dominated by retrospective studies and observational designs with only a small number of randomised trials. This reflects the difficulties inherent in conducting randomised studies in this environment particularly if the service being investigated is in a single site. Individual studies and systematic reviews assessed a range of different outcomes and only one systematic review conducted a meta-analysis for a single outcome, compliance. Broad, relevant quality issues identified by the authors of systematic reviews and individual studies include:

- Different definitions of appropriateness and methods for measuring this outcome
- Different methods for measuring patient satisfaction
- Different clinical assessment systems used to triage calls
- Differences in operational design – 24 hour services versus those only available out of hours
- Differences in the wider healthcare settings services have operated in with consequent variation in the availability of alternatives to ED care such as primary care services.

The consequence is a wide variation in the range of reported outcome results, for example the systematic review by Blank found assessment of appropriateness ranged from 44% to 98%, which makes it difficult to make comparisons between studies and draw firm conclusions about the strength of evidence for some specific outcomes.
Conclusions
There is an existing, substantial evidence base about the operational and clinical effectiveness of telephone based triage and advice services for management of requests for urgent healthcare. We have identified 87 relevant papers from 83 studies, including 8 systematic reviews, reporting a range of outcomes. The most commonly reported outcomes were concerned with accuracy & appropriateness of decision making, patient compliance with advice, safety of decision making and patient satisfaction. Despite the limitations outlined above, some general conclusions can be made about these aspects of telephone triage and advice services.

- Accuracy of decision making is generally high with respect to minimising risk. Similarly, despite wide variation in reported assessments of appropriateness overall, the proportion assessed as appropriate was high in the majority of studies. Where calls have been judged to have been inaccurately or inappropriately triaged the tendency is to assign calls to a higher level of care than needed rather than a lower level. What is less clear is whether this is a function of the triage assessment systems, the individuals using the system or a combination of the two. With the exception of one early NHS Direct study we have found no research that has compared the performance of different telephone triage clinical assessment systems.

- A consequence of this apparent inherent risk averseness does mean that overall telephone triage systems appear to be safe although this may not be efficient. In the small number of studies where adverse patient events or outcomes have been measured these are very low.

- Reported compliance is also variable but overall tends towards a high level although this varies depending on advice given with self-care or ED visits appearing to have higher compliance than advice to contact primary care. This may reflect patient perceptions and preferences and would align with the evidence described in chapter 3 around patient perception of perceived difficulty in accessing primary care.

- Patient satisfaction with telephone triage is generally high and the service well like by users. Although only a small number of studies compared nurse led services with doctor led services, satisfaction appears to be higher in doctor led services.

Other outcomes or aspects of service delivery have been less well investigated and warrant further study.
Only 17 of the included papers assessed the impact of telephone triage and advice services on other services associated with emergency or urgent care. The majority of these studies only assessed impact on single other services (for example ambulance responses, ED attendances, primary care attendances). With the exception of one US study that assessed impact on both ED attendances and primary care activity, only the UK based studies of NHS Direct and NHS 111 have attempted to assess the impact of telephone services on multiple services within the emergency and urgent care system. Whole system impact is a key outcome if one objective of telephone based services is to contribute to improving system efficiency.

The included studies were predominantly concerned with nurse led telephone services. Only 9 papers from 6 studies explored the effects of different types of staff delivering these services. Most of these compared nurse or doctor led services, one compared nurses and paramedics and 2 papers from one study assessed lay operators in a GP out of hours setting. The findings from these studies were mixed with some reporting no differences in appropriateness of decisions between nurses and doctors whilst other found nurses more likely to refer to higher level care than doctors. Acute problems and non-urgent problems appear to be more accurately identified than urgent problems suggesting the latter are more difficult to assess and there is a suggestion higher level clinician assessment may improve accuracy for these problems. Only one study investigated two level triage, (nurse assessment followed by doctor assessment), for a subset of calls. The broad area of optimum skill levels and mix of clinicians and non-clinicians has not been addressed.

Few studies have examined the costs associated with telephone triage and advice services and these have taken different approaches to estimating and reporting costs which makes comparison difficult. The financial benefits of these services both at an individual service and whole system level remain unclear.

Given that a primary objective of telephone triage and advice services has been to improve and simplify access to urgent care there is remarkably little evidence about the impact of these services on access. Only 5 included studies examined impact on access.

These 4 evidence gaps are of particular relevance to the continued development of the NHS 111 service within the NHS. Assuming that NHS 111 will continue to be a principle entry
point for access to urgent care and that the existing clinical assessment system (NHS Pathways) will remain unchanged, the key challenges are based around improving the existing service so that it can fulfil the intended objectives. It is worth remembering that the scale and scope of the NHS 111 service is much greater than the services included in the existing evidence including its predecessor NHS Direct. It is also the case that there have been significant technological advances over the 20+ years that the evidence spans and so evidence from early studies may lack relevance now. Previous services have mostly been small in scale and intended to provide advice and some direction about what service people should access.

The vision for NHS 111 is that it provides broader functions including health information, signposting to other services where patients can take themselves, direct referral to other services on behalf of the patient including ambulances (where needed) and appointments made in real time, and advice. Good decision making at the time of the call is therefore key to an efficient and effective service. The most pressing research issue is therefore that around staffing the NHS 111 service. NHS 111 is unique in that it is a national telephone urgent care access service where the first assessment is made by non-clinical call handlers. The only evidence on impact of using non-clinical call handlers is the existing NHS 111 evaluation studies of pilot services. Qualitative research examining the role of non-clinical call handlers found the work had more in common with clinical work than other call-centre work and the requisite skills need to be carefully incorporated in to training.145 These call handlers are supported by nurse or paramedic clinicians and the NHS England review has stated that the addition of senior (doctor) clinicians to NHS 111 will be considered as part of the ongoing development of the service. Changes to the staffing profile of NHS 111 call handling services will provide a unique opportunity to address the questions around impact of different types of clinicians on accurate and appropriate call assessment and the proportions needed to provide an efficient service. Additional specialist clinical skills such as mental health specialists and pharmacists could also potentially be added to the mix. Adequate follow up of callers would be needed to assess if care pathways are shortened and care really is provided in the right place, at the right time, from the first call and also that access improves. The early research on NHS 111 found it did not substantially change the way the population accesses urgent care but this may have changed since it became a national service.108

Alongside this, the impact of different staffing models on whole system activity can be measured. NHS 111 has been criticised as referring too many patients inappropriately to
higher level ambulance and ED care. The early evaluation of pilot sites did show an increase in ambulance incidents after the introduction of NHS 111 (the reasons for which remain unexplained) but not ED attendances. More detailed evaluation of the accuracy and appropriateness of call assessment decisions would answer some of these questions and identify where there is scope to improve it either through changing the staffing profile or modifying the clinical assessment system.

Changes to the staffing profile, particularly addition of doctors and/or increasing the proportion of clinical advisors, and increased IT infrastructure to support real time referrals will incur costs which will need to be offset by improving whole system efficiency. Robust economic evaluation alongside other changes would provide evidence about the associated costs of providing this complex service, whether it provides value for money and the necessary cost shifting within the emergency and urgent care system needed to plan and support the service in the future.

Finally, evaluation of improvements in the NHS 111 service itself together with measurement of whole system changes in volumes of activity in different associated services and some specific population based research would also begin to address issues about access and whether the service produces real changes and improvements in the way people access urgent care.
Chapter 5 - Management of patients with urgent care problems by ambulance clinicians outside hospital

Introduction

Another key principle of the NHS England review is to provide more urgent care services away from hospitals and so encourage people not to choose A&E services. Enhancing urgent care outside hospital involves a range of services including GP’s, primary care and community services, community pharmacists and ambulance paramedics. There was not scope to consider all of these services within the timeframe for this review. Particular emphasis has been placed in the NHS England review on development of the ambulance service by extending paramedic training and skills so they can manage more people on scene and avoid unnecessary journeys to hospital to achieve this objective. We have therefore focussed our rapid review for this principle on identifying and summarising the existing evidence around initiatives implemented by the ambulance service to support this objective.

Methods

The main inclusion and exclusion criteria, search strategies and review process have been described in Chapter 2. Searches were conducted for the years 1995-2014. For this review specific additional inclusion and exclusion criteria were studies investigating:

Inclusion criteria

- Extended care paramedics (‘community paramedics’, advanced paramedics’, ‘paramedic practitioners’, ‘emergency care practitioners’).
- ‘Treat and refer’ (to community setting)
- ‘Treat and leave’
- Emergency Department avoidance
- Conditions which could be managed at home/in the community
Exclusion criteria

- Acute conditions requiring hospital care

Review process

Studies were identified from database searching and through expert knowledge of the field of interest. In addition to the studies identified through database searching the study team identified 10 additional studies and these were assessed for inclusion in this review. A randomly generated 10% sample of studies from the database searches (n=462) was double sifted by another member of the study team. The reviewers initially agreed on inclusion or exclusion for 97% of studies. The remaining 12 studies were discussed with a third reviewer; of these, six were included and six excluded. The results of the review sifting process are given in Figure 4.
Figure 4  PRISMA flow diagram for ambulance management in the community searches
Results

We identified 7 relevant systematic reviews and within these 64 papers from 57 studies were included although only 21 of these papers met the inclusion criteria for this review. We also identified an additional 12 primary studies not included in the systematic reviews. Formal data extraction was not undertaken for the 21 papers meeting the inclusion criteria and included in systematic reviews as this would have been conducted during the review process. Table 9 lists these 21 studies and which systematic reviews they were included in.

Table 9  Papers included in more than one systematic review

</table>
Studies fall in to two broad groups; those concerned with a focus on investigating expanded professional roles for pre-hospital care providers (predominantly ambulance paramedics) and those focussed on investigating alternatives to transport to ED which encompasses broader professional groups not just those with enhanced skills.

We have summarised the characteristics and findings of the 7 systematic reviews (Tables 10 & 11). Data on the 12 papers not included in the systematic reviews were extracted in to summary tables (Tables 12-14).

<tr>
<td>Bigham 2013</td>
<td>Systematic review of research articles (any design). Search of 3 databases from January 2000 to September 30 2011</td>
<td>Extended scope paramedics working in any type of community paramedic programme</td>
<td>Impact of extended scope paramedics on any patient-related or system-related outcome. Reported outcomes included clinical indicators (ED attendance and length of stay); operational outcomes (time on task and transport rates); patient satisfaction; economic impact; safety; and attitudes and satisfaction of paramedics with training</td>
<td>Eleven articles were included (1 RCT). Community paramedic programmes in the UK, Australia and Canada appeared promising. UK RCT showed benefits for paramedic practitioners over standard care paramedics. Role of CPs is currently unclear and desired outcomes need to be established by consensus. Areas for research included safety of CP programmes; dispatch algorithms to identify patients needing CP services; and deployment models for CP units</td>
</tr>
<tr>
<td>Cooper 2009</td>
<td>Systematic review. Three databases, plus Google, Google Scholar and Journal of Emergency Primary Health Care were searched to July</td>
<td>Ambulance, nursing or medical staff with extended roles in out of hospital emergency care</td>
<td>Appraisal of evidence on impact of new and emerging out of hospital clinician roles on conveyance rates, immediacy of treatment and referral, patient satisfaction, cost savings and inter-professional working</td>
<td>Thirty-four articles were included, with 14 empirical studies analysed in detail. Authors concluded that ECP and PP roles significantly improve conveyance rates, treatment and referral rates and patient satisfaction, with some evidence of financial savings. Areas for research included safety; barriers to implementation; and cost-benefit trade-offs of</td>

<td>Evans 2014</td>
<td>Systematic review. Six bibliographic databases and various grey literature sources were searched from 1990 to March 2012</td>
<td>Paramedics with extended skills; UK ECPs were excluded</td>
<td>Identify evidence of paramedics trained with extra skills and the impact of this on patient care and related services. Skills defined by the British Paramedic Association’s core paramedic competences and associated outcomes</td>
<td>Nineteen articles were included. Authors concluded there is evidence for paramedics assessing and managing patients autonomously to reduce ED conveyance and that this is acceptable to patients and carers. Areas for research included paramedics working with GPs; paramedic referral to hospital departments other than the ED; and paramedics assessing and managing minor acute conditions in elderly patients.</td>
</tr>
<tr>
<td>Hill 2014</td>
<td>Systematic review. Five bibliographic databases plus Google, Google Scholar and the Department of Health website were searched to August 2012</td>
<td>ECPs in any UK setting</td>
<td>Summarise evidence on impact of ECPs on healthcare delivery effectiveness of practice and resource use. Outcomes included staff or patient perceptions of the acceptability or performance of the ECP role; healthcare costs; clinical working practices of ECPs</td>
<td>15 peer-reviewed articles and 6 project reports included. There was support from patients and staff for ECP services. A number of high quality studies reported care processes provided by ECPs as being equivalent to or better than those provided by staff with traditional roles. Prehospital ECPs reduced unnecessary referrals to EDs. Further research needed to establish whether</td>

<td>Brown 2009</td>
<td>Systematic review and meta-analysis. Search of 3 databases to February 2008</td>
<td>US paramedics; Patients for whom 911 or similar emergency call was activated and ambulance transport requested</td>
<td>Comparison of paramedic determinations of need for transport with a reference standard. Primary outcome was NPV of paramedic determinations; other diagnostic accuracy outcomes also reported</td>
<td>Five articles were included, of which only 2 reported full accuracy data. Pooled NPV was 0.91 (95% CI 0.71 to 0.98). Authors concluded there is insufficient evidence to support paramedics determining whether patients need ambulance transport. No explicit research recommendations provided</td>
</tr>
<tr>
<td>Mikolaizak 2013</td>
<td>Systematic review. Six bibliographic databases plus reference lists of included studies were searched to December 2011</td>
<td>Emergency ambulance services; older people (60 years and older) who have fallen</td>
<td>Summarise evidence on non-conveyance, outcomes following non-conveyance and outcomes from alternative care pathways for older people following a fall.</td>
<td>Twelve studies included. Non-transportation rates ranged from 11% to 56%. Non-transported people were likely to access health care following the incident fall: up to 49% had unplanned health care contact within 28 days of the initial fall. One study reported that ECPs reduced subsequent hospital admission compared with standard ambulance crews. Authors recommended research to explore non-ED pathways that can support ambulance services’ decision-making around transportation.</td>

The majority of related research has been conducted in the UK and 8 of the included papers were outputs from two large studies by Mason and colleagues (Mason 2007, Mason 2012). There were only 2 randomised studies and one relevant economic evaluation associated with a larger trial of a community falls service. The main outcomes studied were rates of transportation to Emergency Departments, accuracy and safety of decision making and patient satisfaction. Over 50% of studies included the broad emergency ambulance population with specific populations dominated by older people who have fallen. The small number of studies that have considered costs were also associated with the 3 randomised trials highlighted above.

**Effectiveness**

Six of the systematic reviews found evidence that pre-hospital professionals can successfully reduce the number of patients transported to ED and provide autonomous care and appropriate referral in the community setting. The evidence is predominated by schemes to provide ambulance paramedics with extended and enhanced clinical skills. Two studies showed that hospital admissions were also reduced in patients managed at home by paramedic practitioners and that patients managed at home had no more subsequent health contacts (Mason 2007).

Some of the UK studies involved Emergency Care Practitioners (ECPs), a role open to other health care professionals such as nurses, although in reality dominated by ambulance paramedics, and practiced in settings other than ambulance services. The review by Evans, which was concerned only with paramedics with extended skills, excluded studies of ECPs. The title “ECP” has created problems as the generic “practitioner” part of

the title proved confusing. It conflicts with the regulators ability to ensure patients know who is treating them and was opposed by paramedic professional bodies. The title ECP has been replaced (for paramedics) with titles listed in the paramedic career framework such as specialist and advanced paramedic.

A smaller number of studies have investigated if ambulance clinicians other than those with advanced skills can manage patients out of hospital and reduce transports to ED. Snooks evaluated “treat and refer” protocols for paramedics and found these did not increase the number of patients left at home. More recently, a trial of computer decision support software to aid paramedic on scene decision making about referral to a falls service has shown some promise in increasing the number of patients referred and left at home although the numbers included in the study were small.

Where measured, the evidence on patient satisfaction and acceptability of initiatives to manage patients out of hospital and closer to home is positive. The UK studies on paramedic practitioners and ECPs found patient satisfaction was higher in the groups receiving care from the advanced practitioners than those receiving usual care and other study of ECPs also found high levels of patient satisfaction and that patients found advice and explanations were clearer (Halter 2006, 2007). A positive effect for carers has also been reported. Another study found patients left at home following an episode of diabetic hypoglycaemia and referred to a specialist nurse found high patient satisfaction and increased confidence in managing future episodes.

Only a small number of studies have examined costs but where an economic evaluation has been done management of patients by ambulance clinicians out of hospital has been reported as having lower costs and likely to be cost-effective when compared to conventional hospital care.

Safety and decision making
Reducing transports to hospital is linked to safe and appropriate decision making. Studies of advanced practitioners have shown that decision making is generally safe and appropriate. A number of studies have also examined the accuracy of ambulance clinician decision making around whether or not to transport to hospital for the wider workforce and not just paramedics with advanced skills. The systematic review by Brown assessed the evidence on paramedic decision making about need for transport and concluded there was insufficient
evidence to establish whether paramedics can accurately determine who needs transport. However, only 5 papers were included in this review. More recently, one UK study has assessed the ability of ambulance staff to predict which patients need hospital admission and found they showed reasonable accuracy in determining who needed admission and could correctly identify patients who did not\textsuperscript{177} A US study assessed EMTs ability to identify intoxicated people who did not need transporting to hospital and found there was potential for EMT’s to accurately triage patients to alternatives to ED.\textsuperscript{178} Another recent UK study evaluated the utility and safety of a triage support tools (Paramedic Pathfinder) for deciding which medical and trauma patients needed transporting or could be left at scene.\textsuperscript{179} Sensitivity was high with reasonable specificity however the tools were used in shadow form (all patients were still transported) and there is currently no published evaluation of the tool in real practice.

A small number of more recent qualitative studies have provided some valuable insight in to the difficulties associated with the decision making processes faced by paramedics and advanced paramedic practitioners when deciding whether or not to transport patients. A detailed study on safety and decision making by ambulance staff highlighted that as the need to reduce transports to hospital increased the requirement for appropriate training and education to equip ambulance clinicians for this role also increases.\textsuperscript{176} Two studies on decision making by ambulance staff for patients with epilepsy\textsuperscript{174} and elderly fallers\textsuperscript{175} both identified a need for additional training and support to aid safe decision making as did one Canadian study focussed on management of patients with long term conditions out of hospital.\textsuperscript{182}

Implementation of initiatives
Some studies have highlighted the challenges, facilitators and barriers to implementation of initiatives to enable ambulance clinicians to manage more patients out of hospital although these aspects of service provision are less well reported. The systematic review by Bigham\textsuperscript{146} highlighted issues associated with identifying patients suitable for advanced paramedic practitioner intervention and appropriate dispatching at the time of the emergency call as a potential barrier to using these practitioners effectively. As discussed above, training to support decision making has been identified as a facilitator but also a barrier where this is felt to be insufficient. The effects of integration with the wider urgent and emergency care system on successful implementation have also been raised and in particular the need to have
clear information about patients and about access to alternative care pathways for patients.\textsuperscript{150, 174, 176} Other relevant issues identified which impede patient management out of hospital include conflicting demands of maintaining operational performance to meet response time targets which reduces opportunities for training, barriers between professional groups, a continuing perception that the ambulance service is still primarily a transport service and fear of litigation associated with complex decision making.\textsuperscript{174, 176}

**Quality**

Although there is a substantial evidence base associated with the development of the ambulance service as a provider of out of hospital care, as evidenced by the 7 systematic reviews included in this rapid review, there is a lack of robust, high quality randomised controlled trials. Much of the relevant evidence included in the systematic reviews is derived from the two UK studies comprising a cluster randomised trial of paramedic practitioners\textsuperscript{165} and a community intervention trial of ECPs (Mason 2012).\textsuperscript{168} There is also a single randomised trial of use of Clinical Decision Support Software for management of fallers.\textsuperscript{181} The rest of the evidence is based in a range of study designs which introduce a number of limitations identified by study authors including:

- Use of small convenience samples in some studies which introduce potential bias from self-selection of participants and may not be representative of the intended clinician group
- Use of service evaluation approaches with no control group and therefore reported results do not account for any potential bias or confounding effects
- Studies of decision making where clinicians have recorded intended rather than actual decisions (i.e. patients have still been transported to hospital) which limits applicability to actual clinical practice. Compliance rate in completing questionnaires is often low.
- Important outcomes such as adverse events and subsequent health care utilisation are, with a small number of exceptions, not recorded or reported.

More generally, most studies have been small scale, in single sites and usually involved a sub population of patients and clinicians limiting generalisability to wider clinical practice.
Conclusions

Extended paramedic roles have been implemented in various health systems and settings and, based on a small number of high quality studies appear to be successful at reducing transports to hospital, making safe decisions about the need for transport, delivering acceptable care out of hospital and are potentially cost-effective. The evidence on safety of decision making about need for transport to hospital in the broader paramedic workforce without advanced skills is less clear and questions remain about safety. Studies concerned only with decisions about whether or not to transport to hospital also tend to ignore the important issue that a decision not to transport requires good clinical care to be provided at scene as an alternative. Good quality care out of hospital is about more than just the decision to transport.

The authors of the 7 systematic reviews and 12 individual papers included in this rapid review have made a range of recommendations for further research including:

- Further work on the safety of decision making and development of better guidelines, decision support systems (including CCDS) and training to support decision-making
- Further assessment of the risk of under-triage associated with decision support tools
- Barriers to implementation
- Cost-effectiveness of investment in training and potential cost savings across different settings and patient groups
- Further development and exploration of out of hospital care pathways for a range of conditions to support decision-making as effectiveness of initiatives to reduce transport to ED will depend on availability of alternative pathways and services
- Assessment of the impact of prehospital interventions on ED crowding

These areas warranting further research have direct application to the NHS England review and expectations of an enhanced role for the ambulance service in managing more patients with urgent health problems in the community setting. It could be argued that at least some of these areas, for example resolving issues around safety and cost-effectiveness and wider system impact, are pre-cursors to any widespread adoption of increased out of hospital management of patients by ambulance clinicians. However, pragmatically it is the case that ambulance services in England have been progressively reducing the proportion of patients
they transport to ED over a number of years both through managing more patients at the time of their call (hear and treat – discussed more fully in chapter 4) and outside hospital (see and treat). Currently the mean non-conveyance rate to ED is 37% although this varies between individual ambulance trusts from 22% to 5% [NHS England Ambulance Quality Indicators http://www.england.nhs.uk/statistics/statistical-work-areas/ambulance-quality-indicators/ambulance-quality-indicators-data-2014-15/]

The reasons for this variation are unclear and the HS&DR research programme has already funded research to explore the reasons for this variation (http://www.nets.nihr.ac.uk/projects/hsdr/135475). However, this does illustrate that the ambulance service already manage a substantial number of their calls outside hospital. Given this and the clear important strategic role of the ambulance service in the NHS England review implementation plans, the future questions relevant to the continued development of the ambulance service as an out of hospital care provider are not about if they should be providing this service but how they can continue to expand and improve this aspect of service delivery. There are 4 key evidence gaps that could be addressed to support this process:

- Clearly a key component to achievement of the NHS England plans is development of the paramedic workforce. The available evidence has shown the potential of advanced paramedic practitioners but these have been relatively small scale and likely to have involved highly motivated individuals willing to advance their practice. There is no evidence about the implications of developing the paramedic workforce at scale to achieve national objectives. One of the issues highlighted in the existing evidence is the possible “gap” in decision making skills between paramedics and paramedics with advanced skills. The paramedic workforce is changing with a much clearer professional framework and is rapidly moving towards a graduate based profession but at present it is unknown to what extent this change may reduce this gap. There is a pressing need to begin to investigate the necessary skill-mix of the paramedic workforce and the proportions of paramedics and paramedics with advanced and specialist skills needed to provide a safe and high quality community based service for patients. The implications around the educational and training needs of the paramedic workforce that will be needed to fulfil this enhanced role, at scale, will need to be considered at the same time.

- More broadly and to support paramedic workforce planning some clarity is needed about volume of activity and specifically the proportion of patients who could be
managed outside hospital. Although the NHS England review has a clear view that ambulance services can manage more patients out of hospital it stops short of stating how many patients this might encompass. As stated earlier, we already know that there is substantial variation in the non-conveyance rate to hospital across ambulance trusts in England and it is reasonable to assume there is scope for services with low non-conveyance rates to move towards comparable performance of services with higher rates of non-conveyance. What is uncertain is whether there is a threshold for non-conveyance beyond which the risks of leaving people at home begin to outweigh the benefits.

- The qualitative research studies that have explored in more depth the barriers and facilitators to developing management of patients in the community have highlighted the need to develop robust clinical care and referral pathways for a range of different conditions as alternatives to transport to hospital. Without these pathways, and confidence that onward referrals will be actioned efforts to manage more people at home will be thwarted. Development of pathways is linked to development of robust guidelines and tools to support clinical decision making at scene. This will require wider system collaboration rather than small scale individual local initiatives. It may be the case that not all patients who can be left at home need an advanced practitioner if they can be referred to an appropriate alternative provider. The existing evidence suggests that there is potential for clinical decision support software and triage tools (such as Paramedic Pathfinder) to improve and support decision making and further research in this area is needed but this will need to be aligned to workforce development as graduate paramedics with higher level skills may circumvent the need for this type of triage tool. However, it is likely that as the range of alternatives increases so the need for decision support tools increases.

- The existing research evidence is based in small studies which, although showing local effects on reducing transports to ED have not been at sufficient scale to assess system impacts across a range of services both in terms of activity and associated costs. Expanded care by ambulance services in community settings may reduce ED attendances and hospital admissions but increase contacts with primary care, community and social services. Ambulance services themselves may need additional resources (staff, vehicles and equipment) and have increased training costs to support this expansion of their service. Future evaluation of initiatives to develop paramedic
practice and increase the number of patients managed in community settings needs to assess the impact of these initiatives at scale and at a whole system rather than individual service level.
Chapter 6 - Delivery of Emergency department services

Introduction

The NHS England review 6 has a focus on managing more urgent conditions outside acute hospitals including, for example, urgent care centres. It also recognises the need to provide higher level care for some healthcare problems and sets out a strategy for emergency care that can deliver treatment in the right type of facilities and maximise patient outcomes. The model envisaged includes two types of facility, Major Emergency Centres with highly specialised services and Emergency Centres that can treat most emergency conditions and, where appropriate, refer on to a Major Emergency Centre. A core principle for both centres is the presence of senior clinicians 7 days a week. This “model” has been interpreted to some extent as creating a 2 tier service but in reality reflects current provision and the NHS England states it expects the number of centres to remain broadly the same as the current number of Emergency Departments.

Reviewing the evidence on delivery of emergency department (ED) services poses significant challenges. Unlike the preceding two reviews which had a focussed, well defined method (telephone triage) or aspect (paramedic management of patients out of hospital) of service delivery, provision of ED care encompasses the much broader set of issues associated with whole service delivery. These include organisation and operations, service dynamics (flow), clinical roles of different professional groups, demand, clinical complexity of a heterogeneous population of users and relationships with other parts of the health service. Consequently there is also a vast evidence base of related research.

The commissioning brief for these reviews has a focus on models of delivery. We have not reviewed the evidence on highly specialised and regionalised care (acute cardiac care, stroke, major trauma) as these have been extensively reviewed elsewhere. Instead we have focused this review on the evidence around the organisation and operations associated with delivery of general ED services (which are also provided in Major Centres). The Royal College of Emergency Medicine produced a report in 2014 which identified 13 recommendations for changes needed to build a sustainable and resilient emergency and urgent care system 9. We used some of these recommendations, specifically about delivery of ED care (rather than whole system issues) to further refine the focus. We have therefore conducted two linked but separate rapid reviews.

111
1) A key recommendation is that every ED should have a co-located primary care out-of-hours facility. We have updated an existing related rapid evidence review published conducted in 2010 to assess the current evidence for this model of care.

2) We have also reviewed the broader evidence on ED organisation and operation and on advice from a senior clinician kept the emphasis on ED flow (including front door assessment and back door discharge), the related area of clinician role and the key growing area of managing the complex elderly patients in ED.

Co-location of primary care and ED

Methods
For this review we replicated and updated the search strategy used in a previous rapid review\(^1\) and this is described in detail in chapter 2. Searches were conducted for the years 2009-14. We also applied the same inclusion criteria used in this review.

Inclusion criteria:
- Studies reporting primary data on interventions for managing patients with primary care type conditions, however defined
- Included objective measures attributable to a defined intervention, either within or allied to the emergency department.

Review process
Studies were identified from the updated database search and were supplemented by using the reference list of studies identified and included in a related systematic review recently conducted and in preparation for publication by authors within ScHARR [Shammi et al, personal communication]. This paper identified 4 additional studies and these were assessed for inclusion in this review. A randomly generated 10% sample of studies from the database searches (n=572) was double sifted by another member of the study team. The reviewers initially agreed on inclusion or exclusion for 96.4% of studies and agreed to exclude the remaining 26 studies after discussion.
Results
Nine papers were included in the review, 2 systematic reviews which included 28 individual papers and 7 additional papers.

The results of the review sifting process are given in Figure 5.

A summary of the characteristics and findings of the included papers are given in tables 16 & 17.

One study showed a significant difference in number of prescriptions made by GPs compared with EPs. These two studies showed marginal cost savings from introducing GPs in hospital EDs. Third study failed to identify a significant difference in the number of investigations or admissions to hospital but a significantly greater number of referrals to specialists and prescriptions made by GPs compared with EPs. Insufficient evidence to draw conclusions about the effectiveness and safety of GP versus EPs for non-urgent patients in the ED.

**Summary of findings**

Two systematic reviews\(^{10,196}\) examining the evidence on effectiveness of primary care services associated with ED included findings from 28 studies. Both concluded that, although there was some evidence that locating primary care services within or close to ED could
reduce ED attendances, might save resources by using fewer diagnostics and referrals for admission and potentially could reduce costs, the evidence base to support development of this model of care was weak and based on poor quality studies. Our search identified a further seven, more recent studies which, overall presented more positive findings on the potential benefits of integrating GPs within ED. Two studies in the Netherlands where GPs were located within the ED found process and treatment times were reduced and patient satisfaction increased after the introduction of this service and that there were cost savings. However these were both uncontrolled before & after studies so the influence of other potential confounding factors is unknown. A study of a primary care patient navigation service significantly reduced the likelihood of ED readmission for less frequent primary care-related ED users and produced cost savings whilst a Hospital-integrated general practice (HIGP) service was shown to have potential to significantly reduce the time from admission to discharge and resource use as primary care doctors used fewer diagnostics than ED physicians. A broader study examined longitudinal trends in ED attendances over 3 years after introducing integrated out of hours GP co-operatives. Findings were that overall ED attendances decreased and in particular self-referrals, but referrals from GPs to ED increased as did ED admissions. Unsurprisingly, GP co-operative consultations increased and what is unclear is the net effect of patient movement between these services. Again all of these studies were uncontrolled. The only comparative trial was conducted in the UK and investigated the impact of introducing walk in centres in the vicinity of EDs. This study found that whilst ED attendances decreased in some centres in others there was no change. Overall, there was no evidence of impact on re-consultations, patient outcomes or costs. The lack of success may in part have been due to the walk in centres not having any clear identity and hence were not visible to the public as an alternative to ED. Of the available evidence the most convincing seems to be from models where GPs or primary care professionals are located within the ED itself rather than alongside or as stand-alone units. Intuitively this makes sense as it creates a single “front door” which may reduce confusion for the public and allow more efficient streaming between ED and primary care with a single entry and assessment point. It is also possible that this intervention may be most suitable for simple single episodes and that complex conditions and frequent users need more specialist and sophisticated care. Boerke makes an important point about the influence of general societal and cultural factors on healthcare-seeking behaviour, and suggests that interventions to reduce the amount of “inappropriate” use are likely to fail and strategy might be better
focused on enhancing adequacy of care, and less on trying to match healthcare-seeking behaviour to the services.

**Quality**
The quality of the available evidence is generally poor. Of the 35 included studies there were only 5 randomised controlled trials and a high preponderance of uncontrolled before and after studies which cannot control for other system effects. For example, the study by Thijsen\(^{202}\) acknowledges that closure of hospitals during the study period may have had some influence on the findings. The authors of the 2 systematic reviews identified a range of limitations to the studies included in their reviews including small sample sizes in the form of low response rates, lack of data on patient wait-times, length of hospital stay, adverse effects or mortality and a lack of consideration of patient safety issues.\(^{196}\) The review by Fisher\(^{10}\) also identified the poor research design and reporting of studies including variability in study design and length, sample size, period of follow-up and definitions of primary care/non-urgent type condition. Individual authors of included studies have acknowledged the difficulties of conducting randomised trials in this difficult environment.\(^{198}\) The majority of studies were set in single centres which limits generalisability. This is exacerbated if the focus is a particular group, such as the uninsured, the elderly, or children and may also be limited by the healthcare system an intervention operates in.\(^{199}\) The trial by Salisbury\(^{200}\) identified some additional limitations and important considerations particularly the low quality of available routine data; the need to allow new services time to mature and hence to design studies of sufficient length to detect real effects and the need to conduct studies at scale and assess true impact across a whole system rather than single sites.
ED organisation and operation

Methods

The main general inclusion and exclusion criteria, search strategies and review process described in Chapter 2 have been applied to this review. Searches were conducted for the years 1995-2014. Specific inclusion and exclusion criteria used in this review were:

Inclusion criteria:
- Empirical studies that had evaluated changes to ED service delivery
- Associated with the key areas of ED flow management, workforce specific or management of frail elderly
- Applied to the broad ED population (not specific conditions)

Exclusion criteria:
- Descriptive studies of a service intervention only with no assessment of impact

Review process

Studies were identified from the database search and were supplemented using our internal topic expertise. The searches identified 3539 records. Early in the search sifting process it became clear that, with such a broad range of processes present within ED, the volume of potential inclusions was prohibitive in terms of including and synthesising individual papers or studies. The initial sifting identified a large number of existing, related, systematic reviews and so a decision was made that we would only include these systematic reviews in our synthesis.

Results

22 systematic reviews were included. The results of the review sifting process are given in Figure 6.
A summary of the characteristics and findings of the included systematic reviews are given in tables 19-21.

<td>El Abdulwahid 2015 204</td>
<td>Systematic literature search with assessment of relevance and bias using the Effective Public Health Practice Project (EPHPP) bias tool.</td>
<td>Emergency Department, senior Doctor triage</td>
<td>To review and synthesise studies with the primary aim of investigating the effect of senior doctor triage on emergency department quality indicators (waiting time (WT), length of stay (LOS), left without being seen (LWBS), left without treatment complete (LWTC)</td>
<td>25 studies with a control group were included. Most studies showed that using senior doctor triage improved ED performance measure results. Pooled results from 2/4 RCTs showed a significant reduction in LOS for medium acuity patients (WMD -26.26 min 95%CI -38.50 to -14.01). Two other RCTs showed waiting times significantly reduced when using senior doctor triage (WMD -26 min, 95%CI -31.68 to -20.65). LWBS was reduced in 2 RCTs [RR = 0.79, 95% CI 0.66 to 0.94]. This was similar to most of pre-post study designs. Senior doctor triage had no effect on adverse events or clear benefits for patient satisfaction or cost effectiveness. 9 studies were of moderate quality, 4 were of strong quality and 12 were weak quality.</td>
</tr>
<tr>
<td>Bullard, 2012 205</td>
<td>Narrative synthesis, grouped by outcome</td>
<td>Emergency Department, rapid assessment zones/pods</td>
<td>To synthesise evidence on the use of rapid assessment zones/pods to reduce overcrowding</td>
<td>There were 4 included studies, (1 RCT, 1 controlled trial, 2 before and after studies), with sample sizes between 200 – 12305, representing 23189 participants. Study quality was assessed as weak for 3 of the studies.</td>

<td>Cooke, 2003 Qualitative systematic review.</td>
<td>Emergency Department; assessment/admission wards</td>
<td>To review the advantages and disadvantages of the use of assessment/admission wards</td>
<td>The review reported that rapid assessment zones/pods have the following benefits: Two studies showed a reduction in ED length of stay. This ranged from -20 minutes (95% CI -47.2 to 7.2) to -192 minutes (95% CI -211.6 to -172.4). Three studies showed reductions in physician initial assessment ranging from 8 minutes (95% CI -13.8 to -2.2) to 33 minutes (95% CI -42.3 to -23.6). Two studies showed a reduction in left without being seen, ranging from RR 0.93 (95% CI 0.77 to 1.12) to 0.68 (95% CI 0.63 to 0.73). Low acuity patients found to benefit most from rapid assessment zones, but limited evidence to support implementation.</td>
<td>17 studies included. Most suggest assessment or admission wards are beneficial; they improve patient satisfaction, are safe, reduce length of stay, provide earlier senior involvement and reduce unnecessary/inappropriate admissions. May be particularly useful for certain diagnostic groups, but have little effect if care is already</td>

<tr>
<td>Daly, 2003 Systematic review (comparative studies)</td>
<td>Emergency Department, Short stay observation units (SOUs)</td>
<td>To conduct a systematic review of how short-stay observation units (SOUs) affect the efficiency of healthcare delivery and the quality of services provided.</td>
<td>Reported potential benefits of SOUs are reduced length of stay, improved ED efficiency &amp; reduced cost but between study variation in reported benefits. Length of stay (LOS): One study reported reduced LOS for patients treated with a “rapid” chest pain protocol in a chest pain unit to exclude the diagnosis of myocardial ischaemia. Average LOS for “rapid” protocol patients was 15.4+12.2 hours, compared to 54.6+12.6 hours for routine care. Re-contacts: Two papers examined the impact of SOUs on ED re-contacts for patients with asthma. In one study repeat ED visits within 72 hours increased from 3% to 5% after the introduction of an observation unit for asthma patients. The other reported no difference.</td>
<td>good. Observation wards may reduce ED workload and improve patient flow. Reduced pressure on hospital staff allows more time for important decision making such as diagnosis, ensuring appropriate admissions which may reduce costs. Some studies advise patients should be transferred out within 24 hours to prevent inappropriate use.</td>

| Flores-Mateo, 2012    | Systematic review (n=48)         | Emergency department       | To systematically review the effectiveness of organisational interventions designed to reduce ED utilisation | Most studies were of poor methodological quality. Results were reported in the following categories:  
1) Interventions addressing the supply and accessibility of services (n = 25): 10 studies demonstrated lower ED visits are associated with increased amounts of primary care centres or doctors. Of 3 studies concerned with hospital admission, 2 reported a decrease and one reported no change. 2/9 studies reported less ED use after increasing OOH provision, but results for other studies reported less consistent results and some increase in use. Analysis of all studies showed that ED use is only reduced if primary care is provided by the same team.  
2) Service demand interventions:                                                                 |

</table>

Educational interventions n= 6. Two RCTs found no differences in post intervention ED use. Others reported specific interventions associated with lower ED use were monthly educational group meetings; health education; patient advice; counselling; use of care facilitators. Two studies found a significant reduction in the number of hospital admissions for the intervention groups.

Barrier interventions (gatekeeping/cost) n = 17). 7 out of 8 studies reported ED cost-sharing reduces ED utilization and the other reported a dose-response relationship between co-payment and ED visits reduction. No increases in hospitalizations or mortality rates were reported. Overall, evidence suggests ED cost sharing and interventions to increase access to primary care are successful at reducing ED visits. Other interventions had variable results.

<td>28 studies were included - 13 journal publications; 12 abstracts; 3 Web-based articles. Most studies employed before–after designs; 23 of the 28 studies were considered of weak quality. Pooling of data from two randomised controlled trials (RCTs) found TLPs resulted in shorter ED Length of stay (LOS) compared to nurse-led triage (Weighted Mean Difference WMD = -36.85 min; 95% CI = -51.11 to -22.58). One RCTs showed a significant reduction in the time to physician assessment associated to TLP presence (WMD = -30.00 min; 95% CI = -56.91 to –</td>
</tr>
</tbody>
</table>

Primary care provision within ED may increase patient satisfaction, particularly if waiting times are reduced. The introduction of a co-payment scheme reduced primary care ED attendances by 14.6%. Patient education by itself does not produce a measurable reduction in primary care ED attendances. The unit cost of treating a primary care patient in ED is similar to treating that patient in primary care & providing GPs within ED could potentially reduce costs.

</table>
Summary of findings

Reviews of the evidence associated with managing ED flow

The interventions included in this theme were most commonly concerned with early patient management processes such as triage, initiatives to manage flow within the department such as assessment/observation units and short stay wards and initiatives to reduce ED attendances. The most commonly reported outcome measures were reductions in length of ED stay; the proportion of patients leaving without being seen and ED waiting time. Harding, et al. found reductions in all three when they examined triage with management options against triage with prioritisation only. Katz, et al. found that interventions that developed post-ED plans were generally effective in improving follow-up rates or reducing repeat visits to ED. Porter found the same effect when examining rapid assessment models. Triage liaison physicians were reported to have had an impact in reducing ED lengths of stay, compared to nurse-led triage and senior doctor triage could reduce both waiting times and length of stay in the ED.

Three reviews assessed the evidence on use of observation or assessment units and short stay wards. One concluded that assessment or observation units had potential to produce benefits including facilitating early senior clinician involvement and reducing length of stay and inappropriate admissions but that this may only apply to specific diagnostic groups. This review did highlight that these process benefits reduced workload which in itself could then impact on better decision making. Similarly a review of short stay wards for chest pain and asthma patients found potential to reduce length of stay and produce cost savings but the number of included studies was small and results not consistent. Another review focussed on rapid assessment zone/pod initiatives to reduce emergency department overcrowding and found that although the results appeared to suggest a positive effect, the available evidence to support its implementation was limited and weak. A much broader review by Hoot identified a number of solutions that may potentially mitigate ED crowding including use of observation units, increasing staff, referring low acuity patients out and using queueing theory to manage processes. Flores-Mateo found that interventions that aim to increase access to primary care and ED cost-sharing are effective in reducing ED use. Both this review and that by Leydon reported that patient education programmes did not have a significant impact on patients with primary care conditions using ED.
A review assessing the evidence on using lean processes within ED found that although there was some indication that they may reduce waiting time, length of ED stay and the proportion of patients leaving without being seen the evidence was weak and no studies had examined impact on quality of care or patient outcomes.\textsuperscript{211}

**Workforce**

We have included a small number of systematic reviews that have focussed on assessing the evidence on different professional roles in the ED and particularly changing or expanding roles. A systematic review by Carter and Chochinov\textsuperscript{221} examined the potential impact of Nurse Practitioners (NPs) and found NPs could function as competently as doctors and consistently high rates of patient satisfaction were reported. They concluded that supplementing existing ED staff with NPs can help to manage demand more effectively, especially in high volume EDs and may also have an important role to play in treating lower acuity patients in minor injury units. Another review of management of minor injuries by emergency nurse practitioners came to broadly the same conclusion that this was a safe and effective way of managing this patient group.\textsuperscript{222}

The evidence on the effectiveness of physician assistants was less clear. While they were found to be more reliable in assessing particular medical complaints, were more trusted with performing procedures and were approved of by ED staff and patients, there is limited evidence as to whether they can improve patient flow or are a cost-effective response.\textsuperscript{223} The physician assistant role is well embedded in the US health system but not in the NHS so may be of limited relevance. Workforce issues were raised in several other reviews. The review of evidence on use of Lean methods in ED considered impact on employees and found that Lean thinking may have encouraged frontline staff to take control of their own work and contribute to creating an environment committed to continuous improvement. The increasing ability of staff to take control of their own work was also one of the key findings in the review of rapid assessment models.\textsuperscript{216} In addition, the authors also found that rapid assessment models encouraged team working, collective responsibility and helped to improve communication but also had potential for negative consequences creating longer shifts and more demanding working conditions.

**Managing the frail elderly in ED**

We identified just two systematic reviews that had appraised the evidence on specific management of the frail elderly patient in the ED and both focussed on Comprehensive Geriatric Assessment (CGA), which is a multi-dimensional and usually inter-disciplinary
diagnostic process to assess a frail older person’s condition. Neither study provided conclusive evidence as to the effectiveness of CGA. Conroy, et al.\textsuperscript{224} did not find clear evidence for the benefit of CGA on mortality, readmissions, institutionalisation, functional ability, quality of life or cognition. They were also unable to identify any models of care which realise the benefits of CGA in acute, short-term in-patient care. Nor were they able to find any evaluations for interventions for frail older people who are discharged from Acute Medical Units (AMUs), which are increasingly used in the UK. Graf, et al.\textsuperscript{225} suggested that CGA can have a significant impact across many domains. These include: reducing functional decline and ED readmission. Some of their studies showed that CGA did not have a significant impact on outcomes nor mortality, while others suggested that such an intervention could reduce functional decline. There was mixed evidence over institutionalisation. Applying CGA in the ED was viewed to be time-consuming, with the authors presenting the case for shorter and more routinely applicable alternatives.

The literature around CGA suffers from being limited in nature and of variable quality. Some areas, such as adverse outcomes, are under-researched and very little outcomes data was available, while the small number of studies examined made it difficult to draw meaningful conclusions.

**Quality**

Quality issues were generally the same as those already discussed in the earlier section on GP services in ED. Overall quality of the available evidence is generally poor with a paucity of randomised controlled trials. Only one of the 22 systematic reviews we have included only utilised RCTs in the review\textsuperscript{224} another included 14 RCTs in a review of post discharge interventions but there was a broad range of interventions and settings so general conclusions were difficult to form.\textsuperscript{212} Variable metrics used to assess performance precluded meta-analysis in most of these reviews. As previously, there was a high reliance on before and after studies and the authors of the reviews included here identified a similar range of limitations as previously discussed such as poor study design, small sample sizes. Very few studies considered the cost consequences and cost effectiveness of interventions and inclusions were dominated by single centre studies with consequent implications for generalisability and none considered whole system effects and the impact this may have on the success or failure of particular interventions. Four of the systematic reviews we have included are now quite old – two published in 1998\textsuperscript{217, 218} and two in 2003.\textsuperscript{206, 207} Delivery of emergency and urgent care
continues to develop and operates in a rapidly changing environment so, although not without some value, at least some of the studies included in these reviews and the inferences drawn from the results may have limited relevance to current service provision.

We have also conducted a simple quality assessment of the 22 systematic reviews included in this section using four basic methodological criteria: adequate search, assessment of risk of bias in included studies, use of an appropriate method to synthesise the studies (e.g. meta-analysis or narrative synthesis) and whether the authors’ conclusions reflected the evidence presented. Critical appraisals from the Database of Abstracts of Reviews of Effects (DARE) were used if available. For other reviews, quality was assessed by one researcher using the full text of the review. The results are given in Table 22.

</table>
Overall, the reviews performed reasonably well against the four criteria. All except two of the reviews had an adequate search (covering at least two databases and/or other sources). Two reviews only searched MEDLINE or PubMed, which means they are may not have located all relevant studies.

Risk of bias of included studies was assessed using recognised checklists or scales in 13/22 reviews. In the remainder, risk of bias was either not assessed or no results were reported. In the absence of a risk of bias assessment, it is more difficult to assess the strength of the evidence underlying the review’s conclusions.

Seventeen reviews were judged to have used an appropriate method to synthesise the studies. In most cases a narrative approach was used because the included studies were too heterogeneous for meta-analysis. Reviews that provided a narrative discussion of the included studies without any description of methods of synthesis have been classified as ‘unclear’.

In most reviews (14/22) the evidence presented was judged to support the authors’ conclusions. Reviews where the DARE appraisal considered that the author’s conclusions were potentially unreliable or should be treated with caution have been scored as unclear.

### Conclusions

This rapid review attempting to assess the evidence on different models of delivering ED services has been particularly challenging. The broad focus on a whole service means there are a whole range of potential areas to assess that are of pressing concern including operational processes at different stages as patients progress through an ED and the issues associated with that (front door assessment, flow through the department, exit block); workforce issues (who does what, when, how many) and the associations with the wider emergency care or hospital system that impact on performance. The more focussed review on co location of primary care within ED did identify a relevant and manageable set of existing systematic reviews and primary research studies to allow some synthesis of evidence.

Practical constraints meant that for the second part we have only been able to conduct a “review of reviews” but, given the extensive evidence available, we have probably not done this topic area justice and there will be many relevant aspects that we have not considered at all and given the complexity it has been difficult to identify clear and unambiguous evidence.
gaps. However, the review has highlighted some areas that are worth further consideration and can guide future research in this area;

- In the process of conducting these rapid reviews we have conducted extensive searches and have created a substantial library of relevant research articles. Given the complexity of the topic area, more focused reviews could be carried out utilising the work already done here with, where necessary targeted focused additional searches. Because of the complexity and because of the rapidly changing environment and pressure on services to implement change there are already policy and guidance documents from a range of sources such as the Royal College of Emergency Medicine setting out interventions that should be implemented\(^2\) many of which may not have a solid evidence base. Before further more focused reviews are carried out it may be prudent to consult with the RCEM and identify which specific topic areas would benefit from a more detailed analysis

- Although management of the frail elderly is seen as a key area for development\(^9\) there is remarkably little research on interventions to improve care for this population. There is scope to identify more recent primary studies from our existing search library to supplement the two existing systematic reviews as both were published in 2011 and further review this important area

- One clear evidence gap identified from the research we have appraised here is lack of studies that take a broader system approach to identifying, implementing and evaluating interventions to try and improve emergency and urgent care. This has important implications for future service design and planning. Future ED focussed studies could be broadened out to encompass these wider system issues. If this is ignored there is always a risk that some specific interventions may appear to be inefficient or not deliver intended benefits at an individual service level and abandoned when in fact the benefits may be being achieved elsewhere or some external system issue may be inhibiting an intervention from working optimally.
Chapter 7 - Emergency and Urgent care Networks

Introduction

The final element of the NHS England review is focused on the development of broad emergency and urgent care networks with the aim of connecting services together as a system. The vision for these networks is that they will reduce boundaries between hospital and community based services and support information flow and expertise across sectors so patient care can be delivered in the most appropriate and convenient setting. The review initially envisaged major emergency centres would take the lead in this development but subsequently NHS England have outlined a wider model based on a combination of strategic and operational functions with no specification on lead.

https://www.england.nhs.uk/2014/05/30/jonathan-benger-2/

The emphasis on providing emergency and urgent care has seen a shift and consensus that a whole system approach is needed and emergency and urgent care networks are seen as being central to the achievement of system wide objectives. In this review we have attempted to identify if there is any empirical evidence on the organisation, function and effectiveness of emergency and urgent care networks in improving the delivery of emergency and urgent care.

Methods

The methods and search strategy have been described in detail in chapter 2. Searches were conducted for the years 1995-2014. For this review the specific inclusion and exclusion criteria were:

Inclusion criteria

- Focused on whole system emergency and urgent care
- Network operating models used in practice
- Empirical assessment of network performance or effectiveness

Exclusion criteria

- Descriptive studies with no assessment of effect
The results of the searches are given in Figure 7.

Figure 7  PRISMA flow diagram for emergency and urgent care networks searches
Results

We found no relevant papers that fulfilled the inclusion criteria, that is, provided a description of an operating emergency and urgent care network model with some empirical evidence of how it performed and produced impact on healthcare delivery. There were 21 papers that were related to networks and the delivery of healthcare but these were predominantly related to:

a) Descriptive studies of clinical networks for specific conditions or patient groups but with no assessment of effect. For example, a clinical network to provide care pathways for aboriginal and Torres Straights populations with acute coronary syndromes, a model of a Trauma Network in the USA and, perhaps more relevant, a network for integrating ambulance services and acute hospitals in the Netherlands. The description for this network included a statement that Government policy had been put in place to monitor development but no outputs have been identified.

b) Studies reporting data on activity within clinical networks for specific conditions such as stroke, trauma, and primary or community care and ST elevation myocardial infarction. Most of these studies claimed clinical networks had improved care by, for example increasing numbers of patients admitted to specialist facilities, receiving thrombolysis for stroke and improving mortality from trauma but all of them reported current activity and had not made any assessment of differences in care compared to before the network became operational and therefore if the network had improved care.

Perhaps more useful in terms of providing insights in to factors that aid or inhibit network function and so provide lessons for emergency and urgent care network development are the small number of qualitative studies that have examined this area in more detail. One study of healthcare professional’s perceptions about functioning of a gerontological network highlighted 3 key characteristics – the central role of GPs in co-ordinating care; geriatrician’s intervention in assessment of older patients needs and the interface between hospitals, GPs and homecare. Lack of collaboration hindered network function. A UK study of the network governance lessons from a programme aimed at improving care for older people and reducing emergency bed days identified some helpful lessons. The study found features associated with effective network governance included selection of a small number of evidence based services; co-ordination by a network based strategic group with clear...
responsibility for implementation at operational level and a “joined at the top” implementation group.

There were a small number of papers that did have an emergency and urgent care network focus but were of limited value in terms of providing evidence on successful and effective network models. One UK paper describes attempts to develop an early emergency care system in Surrey\textsuperscript{239} although this is now old, the NHS environment has changed substantially since then and there appears to be no subsequent outputs demonstrating success or further development. Two papers emerged from a US consensus conference on integrated networks of emergency care. One sets out a conceptual framework for how categorise, designate and regionalize services within a network and identifies a range of research opportunities needed to support this process including contributing to design, processes, utility and impact on patient outcomes.\textsuperscript{241} The other sets out a research strategy for developing methods for defining and measuring success in emergency care networks and the infrastructure need to support it including identifying key metrics, scaling, network data systems and data linkage.\textsuperscript{242} These two papers set out an “aspirational” view of future emergency care networks and there may be some value in considering the conceptual approaches they have described when thinking about network development but they do not provide any information on how these aspirations might be operationalised in to a functioning network.

**Conclusions**

We have found no evidence base on how to best organise and operate an emergency and urgent care network with associated empirical evidence to demonstrate the effectiveness of a network model in managing and improving delivery of care. There is some related evidence from other types of clinical networks but these are very focused in their remit. Whilst they may provide some useful insight for network development, strategies that work in improving care for specific conditions or groups of patients with clear and well developed care pathways may not be transferable to the complex, broad population, whole system based focus of emergency and urgent care networks. Literature on networks within the specific topic area of emergency and urgent care is scant and confined to descriptive articles or “think pieces” about the conceptual and aspirational frameworks for network based models rather than examples of functioning network models. We conducted some descriptive research on this topic for the Department of Health in 2007 which described a small number of embryonic
emergency and urgent care networks in existence at the time\textsuperscript{243} but which subsequently disbanded or changed with multiple re-organisations. This report did suggest some principles for network development based on the experiences of the early study sites which have been translated in to the NHS England suggested model but we did not measure network effectiveness.

Given that emergency and urgent care networks are a key component of the delivery of the NHS England review there is remarkably little evidence and information available to inform this development. Anecdotally, health economies are building networks but there is no information available at a national level about the structure and operating models of existing networks or indeed how many there are. It is likely that networks are developing in isolation which limits opportunities for sharing experiences about network model design, development and implementation.

There are some key and pressing research activities which could support emergency and urgent care network development:

- A more detailed and targeted rapid review could be undertaken to further explore the more theoretical literature about network model development and implementation to supplement the small descriptive evidence we have identified. More detailed synthesis could provide evidence around central components and strategies for successful network development that could be used to underpin network development now taking place.

- Of course, it may be the case that this additional evidence review is too late and nationally network development is already underway although there may still be some value to modifying existing models. There is a paucity of information about activity in an area of viewed as being of such strategic importance to delivering a whole systems approach to emergency and urgent care. Some rapid scoping research to identify and map current emergency and urgent network development nationally could provide useful information of numbers, size, models, state of maturity etc. This could be supplemented by more qualitative work to identify the more detailed issues associated with developing and implementing a network model including challenges, barriers and facilitators which can then be shared

- A programme of research to evaluate emergency and urgent care progress using case study sites identified from the work suggested above. This would need to be a long-term strategy involving comparing different models of networks to assess processes,
operation and management and ultimately to measure effectiveness and the extent to which different models change and improve the delivery urgent care and achieve the objectives set out in the NHS England review plan.

- Information will be a central component of network function. The earlier chapter on demand set out the importance of whole system information systems which will allow better understanding of demand and inform planning of services needed to meet that demand. Subsequent chapters have highlighted the need to evaluate service developments in terms of whole system as well as individual service impact. Development of robust and linked patient based data systems will be needed to support these activities. Research to better understand the information needs of emergency and urgent care systems and networks and map this to existing information system development by other parts of the NHS, for example the Academic Health Science Networks, Health & Social Care Information Service, NHS England, and local initiatives could inform the development of a coherent national plan for network information system development.
Chapter 8 –Discussion and Conclusions

Summary of main findings

We have conducted five separate rapid reviews spanning a range of themes relevant to the NHS England review of emergency and urgent care. A comprehensive discussion and conclusions are provided at the end of each review chapter. The main findings from each review are briefly summarised here.

Demand for emergency and urgent care

Despite serious concerns about rising demand and the impact this has on health services there is remarkably little empirical evidence that can fully explain why this has occurred. Much of the evidence has focused on either individual services or populations such as the elderly. Although there is a substantial evidence base that has explored patient reasons for accessing urgent care there is a lack of any sophisticated understanding about what is driving demand for individual emergency and urgent care services and no published literature on whole system demand. In the UK the only recent evidence about whole system demand is that available in the evaluation examining the impact of NHS 111 pilot sites and within this a lack of any data on in hours GP urgent care means the whole picture remains unclear. There is a broad literature of discrete studies on individual factors that may influence demand. The evidence key gaps and challenges identified from the existing evidence relate to:

- A need to examine demand from a whole system perspective and gain better understanding of the relative proportions of demand for different parts of the system and the characteristics of patients within each sector.
- Development of research studies that build on the existing knowledge about factors which may be influencing demand and the contribution each one makes and map these in to a coherent system model. This would then support the development of service design and planning to meet current and future needs of local populations.

Telephone triage and advice

There is an existing, substantial evidence base about the operational and clinical effectiveness of telephone based triage and advice services for management of requests for urgent
healthcare. Overall, these services provide accurate, appropriate and safe decision making, patient compliance with advice is generally high as is patient satisfaction. Where calls have been judged to have been inaccurately or inappropriately triaged the tendency is to assign calls to a higher level of care than needed rather than a lower level so while services appear to be safe they may not be efficient. Evidence gaps and aspects of service delivery that warrant further study include;

- Further assessment of the whole system impact of telephone access services for emergency and urgent care, including the associated costs, to establish how it contributes improving system efficiency.
- More focused research on the broad area of the optimum requirements for different skill levels needed in the NHS 111 service which provides a unique mix of non-clinical, clinical and senior/specialist clinical professionals
- More detailed evaluation of the accuracy and appropriateness of call assessment decisions would help answer some of the questions about the appropriateness of referrals made by the NHS 111 service and identify where there is scope to improve it either through changing the staffing profile, modifying the clinical assessment system or developing better referral pathways.

Management of patients with urgent care needs by the ambulance service in community settings

Extended paramedic roles have been implemented in various health systems and settings and, based on a small number of high quality studies, appear to be successful at reducing transports to hospital, making safe decisions about the need for transport, delivering acceptable care out of hospital and are potentially cost-effective. The key evidence gaps and areas for further research we have identified include;

- Further work on the development of methods to support paramedic decision-making in the community together with development and assessment of out of hospital care pathways for a range of conditions that mediate safe management in the community.
- More detailed study on the necessary skill-mix of the paramedic workforce, optimum proportions of paramedics and paramedics with advanced and specialist skills needed to provide a safe and high quality community based service for patients and the
educational and training needs to support this enhanced role at scale. The potential impact of increasing paramedic prescribing rights will also need to be considered.

- More accurate estimations of the likely proportion of patients who could be safely managed outside hospital to support paramedic workforce planning.
- Further evaluation of the impact of initiatives to develop paramedic practice and increase the number of patients managed in the community is needed to assess the impact of these initiatives at scale, at a whole system level and the cost consequences.

Models of service delivery in the Emergency Department

Attempting to assess the evidence on different models of delivering ED services has been particularly challenging as there is a substantial range of potential areas to assess. The more focussed review on co location of primary care and ED identified potential for this initiative. Practical constraints meant that for the second part we have only been able to conduct a “review of reviews” and given the extensive evidence available and complexity of the subject area it has been difficult to identify clear and unambiguous evidence gaps. The review has highlighted some areas worth further consideration;

- More focused reviews could be carried out utilising the work already done here with, where necessary, targeted and focused additional searches. Because of the complexity and the rapidly changing environment some consultation with the Royal College of Emergency Medicine would help to identify which specific topic areas would benefit from a more detailed analysis.
- Management of the frail elderly is considered a key area for development but there is little evidence on interventions to improve care for this population. There is scope to identify more recent primary studies from our existing search library to supplement the analysis of 2 related systematic reviews.
- One clear evidence gap is the lack of studies conducted at scale and that have considered wider system effects and impact. Given the emphasis on developing co-located primary care services within ED this is one area where there is a clear opportunity to begin to undertake these broader studies.
Emergency and Urgent Care Networks

We have found no evidence base on how to best organise and operate an emergency and urgent care network or any empirical evidence on effectiveness of a network model in managing and improving delivery of care. There is some related evidence from other types of clinical networks but these are very focused in their remit. Whilst they may provide some useful insight for network development, strategies that work in improving care for specific conditions may not be transferable to the complex, broad population, multiple service based focus of emergency and urgent care networks. Literature on networks within the specific topic area of emergency and urgent care is scant and confined to descriptive articles. Given that emergency and urgent care networks are a key component of the delivery of the NHS England review there is a significant evidence gap and hence some key and pressing research activities which could support emergency and urgent care network development;

- A more detailed and targeted rapid review could be undertaken to further explore the more theoretical literature about network model development and provide evidence around central components and strategies for successful network development.
- Network development is already underway so some rapid scoping research to identify and map current emergency and urgent network development nationally could provide useful information of numbers, size, models, state of maturity and issues associated with developing and implementing a network model.
- A programme of research to evaluate emergency and urgent care network progress using case study sites to compare different models of networks and assess processes, operation and management. In the longer term, studies are needed to measure effectiveness and the extent to which different models change and improve the delivery urgent care and achieve intended objectives.

Evidence sources

For some themes a substantial proportion of the existing evidence came from the UK. In particular 85% of the included studies on expanded roles for paramedics were conducted in the UK, and 37% of the studies on telephone triage. A relatively small proportion of studies on providing primary care in ED (17%) were conducted in the UK. No studies on trends in demand came from the UK but almost half (48%) of the studies examining patient reasons for accessing urgent care came from the UK.
Common themes across subject areas

We have conducted five separate reviews focused on specific areas of service delivery and the synthesis of evidence for each individual review revealed a number of common themes that spanned one or more topic areas. This fits with the view that delivery of emergency and urgent care needs to be viewed from a whole system perspective and highlights the clear interdependencies between the different system components that contribute to efficiency and effectiveness.

Although the theme on understanding demand for urgent and emergency care is not a key theme in the NHS England review, we included it in this rapid review to provide context on the underlying issues that are contributing to pressure in the emergency and urgent care system and hence the need for service change. The issues and evidence gaps identified from the analysis of evidence on trends in, and characteristics of, demand were relevant to several subject areas. The most highly relevant was emergency and urgent care networks. The envisaged primary function of a network is to design and plan an emergency and urgent care system that can meet the needs of a heterogeneous and changing population with a range of complex health problems ranging from acute, life-threatening to minor and chronic illness and injury. To do this a detailed understanding of the profile of the population accessing care, the different types of care they will need and the relative proportion of people requiring different types of service within the system is needed. The identified need to develop more sophisticated models that map demand and the needs of local populations, and can begin to estimate how this will change as population characteristics change, has direct relevance to the potential successful functioning of an emergency and urgent care network. At an individual service level this also has implications for the success of the expected changes in delivery of care. For example, clear estimates and thresholds for the likely proportion of patients who could be safely managed in the community by the ambulance service would inform ambulance service resource and workforce planning. Similarly, initiatives in the Emergency department to better manage specific patient groups, needs information on the likely volumes of patients who, for example, will be suitable for GP care in a co-located primary care unit or specialist major trauma or frail elderly care service.

System designed and developed care and referral pathways – The need for system wide, integrated care and referral pathways was highlighted in the telephone triage and advice and
management of patients in the community by ambulance clinicians themes. In both cases this was seen as critical to further development of these services if they are to operate efficiently and fulfil their potential. The development of these pathways and testing their effectiveness links to the functioning of networks.

Whole service and system impact – a common theme across all three service delivery related reviews was the lack of evidence about the impact of initiatives and interventions at scale. The available evidence is based almost exclusively on evaluations of single initiatives in single centres. This means that, for example, the impact of NHS 111 on delivering system benefits by directing people to appropriate care nationally or at single services level, now that services are much bigger than the pilot services, is unknown. Likewise, although there is good evidence that paramedics can safely manage people in the community, the implications for scaling up interventions for ambulance services and associated primary and community care services, particularly as the desired proportion of patients managed in this way increases, and the impact on, for example ED crowding, is unknown. The impact of scaling up initiatives on both individual and whole system activity, effectiveness and costs is a clear research gap. A final and related theme is that future evaluations of initiatives should be of sufficient length to allow the intervention to mature and function as intended. The risk of not doing this, and of only evaluating the impact on the “host” service rather than the system, is that promising and potentially effective interventions are abandoned, not through lack of evidence but lack of the right sort of evidence. Well functioning networks with robust information systems will be essential to enabling measurement of whole system impacts and costs.

Limitations

The scope of this rapid review and volume of evidence included means we have not been able to conduct a detailed analysis of the quality of the evidence base but we have provided a broad assessment and commentary of relevant issues in each of the separate review chapters. We have included a substantial number of systematic reviews within the review and have drawn on the findings of these studies to identify significant methodological issues. In addition to the limitations around lack of scale and measurement of system impact already discussed some key themes have been identified that are common across the reviews;
• Overall, the evidence base on effectiveness of different models of care for delivering emergency and urgent care is weak. Only a small number of interventions have been evaluated using randomised controlled trial designs. It is acknowledged however that this is a difficult environment in which to conduct this type of study.

• There is a high reliance on uncontrolled before and after studies within the overall evidence base with consequent serious limitations on interpretation of findings. The majority of studies were single site and small in scale with small sample sizes. This makes generalisability difficult, particularly in terms of the relevance to different health systems. There is a lack of population based studies to inform development of emergency and urgent care systems and services.

• The majority of studies have measured processes such as times, attendance or contact rates, re-admission and re-contact rates to assess effectiveness. With a few exceptions, patient outcome measures have been confined to patient satisfaction and there has been little consideration of important patient outcome measures concerned with safety such as adverse events. The reviews on telephone triage and management of patients by paramedics in the community did identify studies that included patient safety.

• Little attention has been paid to the costs and cost effectiveness associated with interventions.

There are some limitations to the rapid review method we have used. Firstly, we have not been able to exhaustively search for and synthesis all the relevant literature for each of the five themes. We have drawn extensively on existing systematic reviews and only extracted detailed information on primary studies not included in these reviews. This has allowed us to provide a comprehensive overview of the existing evidence base for each theme. However, this was a particular limitation for the review of models of care for delivering ED services. For this theme we only included systematic reviews and therefore have not been able to confidently identify the related evidence gaps. This theme warrants additional, more focussed reviews.

Secondly, emergency and urgent care encompasses a broad patient population, range of services and related factors. Given the potential scope and scale we have used a framework to guide the reviews based in the key policy objectives for emergency and urgent care set out in the related NHS England review in order to provide focus and relevance. This framework also guided the systematic search strategies tailored to each individual review but given the
scope we have further restricted the focus of two themes (helping people get the right advice and managing more urgent care outside hospital) to the specific areas of telephone based triage and advice and management of patients by paramedics in the community respectively. This does mean that the broader literature on community based urgent care services has not been addressed.

Thirdly, although using the framework provided structure that enabled us to synthesis a large body of evidence in a short timeframe, it does mean there are related themes and subject areas that have been excluded from this review. The most obvious gap is a separate review of models of urgent care within primary care. There is significant overlap within the existing reviews, for example telephone triage, management of patients by paramedics within the community setting and provision of primary care services within the emergency department. However, there may be more specific evidence we have not considered. There is scope to conduct an additional review within this area utilising the search libraries we have generated for this review. We have also not considered the specific but important issues related to the emergency and urgent care workforce such as education, training, skills, recruitment and retention. This may also warrant and additional review although it would be large in scope as there is a wide range of professional groups to consider.

Finally, the short time frame and volume of included material meant we were not able to include any PPI input in to this review. However, this perspective will be important when considering future research commissioning. We have identified a substantial number of evidence gaps which will need to be prioritised and PPI assessment of those gaps and questions will be of value in understanding which ones are most important to patients and the public and which need most urgently addressing.
Conclusions

We have conducted five separate rapid evidence reviews on themes related to the delivery of emergency and urgent care in the NHS. These themes were trends in and characteristics of demand; telephone triage and advice; management of patients in the community by ambulance clinicians; models of service delivery in the Emergency Department and Emergency and urgent care networks.

We have found there is a paucity of evidence to explain the complex reasons that have driven the increases in demand for emergency and urgent care and the detailed characteristics and consequent service needs of the population. There exists a considerable evidence base on the effectiveness of some interventions to improve service delivery but the evidence base overall is weak and based in small single site studies with no assessment of impact at scale or on the wider emergency and urgent care system. A small number of interventions have been robustly evaluated. The delivery of emergency department care is complex and multi-dimensional and it was beyond the scope of this review to identify clear evidence gaps. Further more focused evidence reviews are needed in this area. There is no evidence to support the development of emergency and urgent care networks.

We have identified a number of evidence gaps across the reviews. The gaps that appear to be in most immediate need of addressing are:

- Research to characterise and map demand at a population level and link this to service need so that emergency and urgent care systems can be designed that can effectively, efficiently and safely respond to patient needs.

- An assessment of the current state of play in the development of emergency and urgent care networks and longer term evaluation of the effectiveness of different network models to identify how best networks can deliver NHS England objectives.

- Expanding the current evidence base on existing interventions that are viewed as central to delivery of the NHS England plan, such as increasing the number of patients managed by paramedics in the community, by developing integrated care pathways and assessing the implications of increasing the intervention at scale. Measurement of the costs and system impact will be critical to the assessment of effectiveness and resource requirements needed to support expansion.
Although not an evidence gap, a clear theme that emerged across the reviews was the need for robust, high quality and linked patient data to support service planning and measure whole system benefits and costs and support research. This may need to be addressed alongside any newly commissioned research studies.

There is also a need to plan and design better quality research studies. Some of the problems associated with existing research studies have been highlighted above. Future research will need to address these problems. The broad range of questions evident from the research gaps means a range of designs will be needed to adequately answer these questions. It is not possible to be prescriptive as each question will need a different approach but there is a clear need to move away from uncontrolled studies and better use of quasi-experimental observational studies that do allow comparison against current practice. Evidence gaps concerned with scaling up interventions would benefit from mixed methods approaches that can consider a range of associated issues. Clinical effectiveness may have been demonstrated but translating this into common practice needs consideration of both the population (quantitative) effects across multiple sites or whole systems and, as importantly, the “real world” processes that effect change and mediate successful adoption of new ways of delivering services. Valuable knowledge can be gained from more qualitative studies that can identify the factors and processes that contribute to success or failure of service change. This is linked to the clear lack of consideration of workforce implications evident in the existing evidence. Future studies, particularly those concerned with scaling up, cannot ignore this component and specific studies providing a primary assessment of assessment of workforce and skill mix requirements may need to be a precursor to any large scale expansion of interventions. Existing studies have also been limited by only measuring short term process and outcome changes and future studies could make better use of, for example, interrupted times series designs to provide a more robust assessment of the impact of service changes in the longer term. Robust economic evaluations should also be conducted alongside any changes to assess cost-effectiveness and also the broader cost shifting that occurs around an emergency care system when large scale service delivery changes are implemented.

There are significant problems within the emergency and urgent care system in the NHS. As a consequence there is pressure to instigate change and services are operating in a rapidly changing environment. Specific programmes such as the NHS England review delivery plan refer to a number of existing pilot schemes and interventions under development. There are also broader programmes across the NHS that may also have an impact on emergency and
urgent care such as the move to 7 day working, the Prime Ministers Challenge Fund to improve access to primary care [http://www.england.nhs.uk/ourwork/qual-clin-lead/calltoaction/pm-ext-access/]. Vanguard sites for new models of care deliver [http://www.england.nhs.uk/ourwork/futurenhs/5yfv-ch3/new-care-models/] and local initiatives. These programmes mean that there are already potentially large numbers of relevant initiatives already underway or in development but it is difficult to identify the range and scope of existing projects. Before new research to address evidence gaps is commissioned it may be worth considering commissioning a preliminary project to identify and map existing plans and initiatives to distinguish if any evaluation research is already underway, whether the planned evaluation is robust and whether there are potentially suitable initiatives that are at development stage but have no evaluation plan in place. This could reduce duplication of effort and help ensure new model of care are rigorously assessed before they are adopted on a large scale.
Acknowledgements

The NIHR HS & DR team

Professor Suzanne Mason, University of Sheffield – For providing assistance with identifying key components of Emergency Department processes and access to related papers currently in press & in preparation.

Dr Matthew Booker, University of Bristol – For providing access to references included in a recently completed related review undertaken as part of an NIHR Postdoctoral research fellowship.

Professor Andy Newton, Chair of the College of Paramedics – For advice on current developments in paramedic education.

Contribution of authors (listed in alphabetical order)

Mr Daniel Bradbury (Medical Student) undertook data extraction in to summary tables for the review on demand for urgent care.

Mrs Anna Cantrell (Information specialist) contributed to the proposal writing, designed and ran the literature searches and contributed to report writing.

Dr Duncan Chambers (Research Fellow) undertook reference sifting, data extraction in to summary tables, evidence synthesis and contributed to report writing for the review on management of patients by ambulance clinicians in the community.

Mrs Joanne Coster (Research Fellow) undertook reference sifting, data extraction in to summary tables, evidence synthesis and contributed to report writing for the review on telephone triage.

Professor Elizabeth Goyder (Professor of Public Health) contributed to the proposal writing.
Dr Emma Knowles (Research Fellow) undertook reference sifting for the review on management of patients by ambulance clinicians in the community.

Mr Viet-Hai Phung (Research Assistant) undertook reference sifting, data extraction in to summary tables, evidence synthesis and contributed to report writing for the review on models of care in the Emergency Department.

Ms Janette Turner (Senior Research Fellow) undertook reference sifting and evidence synthesis for the review on demand for urgent care; undertook reference sifting, data extraction in to summary tables and evidence synthesis for the review on emergency and urgent care networks; contributed to report writing including the discussion and conclusions and managed the project.
